Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

Description**Background of the Invention**5 Field of the Invention

[0001] The present invention relates to methods for coating and/or encapsulating surfaces and three-dimensional objects with cross-linked networks of water-soluble polymers.

10 **[0002]** Microencapsulation technology holds promise in many areas of medicine. For example, some important applications are encapsulation of cells for the treatment of diabetes (Lim, F., Sun, A.M. "Microencapsulated islets as bioartificial endocrine pancreas", (1980) *Science* 210, 908-910), encapsulation of hemoglobin for red blood cell substitutes, and controlled release of drugs. However, using the prior art methods, the materials to be encapsulated are often exposed to processing conditions, including heat, organic solvents and non-physiological pHs, which can kill or functionally impair cells or denature proteins, resulting in loss of biological activity. Further, even if cells survive the 15 processing conditions, the stringent requirements of biocompatibility, chemical stability, immunoprotection and resistance to cellular overgrowth, of the encapsulating materials restrict the applicability of prior art methods.

20 **[0003]** For example, the encapsulating method based on ionic crosslinking of alginate (a polyanion) with polylysine or polyornithine (polycation) (Goosen, et al., (1985) *Biotechnology and Bioengineering*, 27:146) offers relatively mild encapsulating conditions, but the long-term mechanical and chemical stability of such ionically crosslinked polymers remains doubtful. Moreover, these polymers when implanted *in vivo* are susceptible to cellular overgrowth (McMahon, et al., (1990) *J. Nat. Cancer Inst.*, 82(22), 1761-1765) which over time restricts the permeability of the microcapsule to nutrients, metabolites and transport proteins from the surroundings. This has lead to starvation and death of encapsulated islets of Langerhans (O'Shea, G. M. et al. (1986) *Diabetes*, 35:943-946).

25 **[0004]** Thus, there remains a need for a relatively mild cell encapsulation method which offers control over properties of the encapsulating polymer and yields membranes in the presence of cells which are permselective, chemically stable, and very highly biocompatible. A similar need exists for the encapsulation of biological materials other than cells and tissues, as well as materials contacting biological materials.

30 **[0005]** Materials are considered biocompatible if the material elicits either a reduced specific humoral or cellular immune response or does not elicit a nonspecific foreign body response that prevents the material from performing the intended function, and if the material is not toxic upon ingestion or implantation. The material must also not elicit a specific reaction such as thrombosis if in contact with the blood.

35 **[0006]** Gels made of polymers which swell in water to form a hydrogel, such as poly(hydroxyethyl methacrylate) (poly(HEMA)), water-insoluble polyacrylates, and agarose, have been shown to be useful for encapsulating islets and other animal tissue (Iwata, et al., (1989) *Diabetes*, 38:224-225; Lamberti, et al., (1984) *Appl. Biochem. Biotech.*, 10, 101-105 (1984). However, these gels have undesirable mechanical properties. Agarose forms a weak gel, and the polyacrylates must be precipitated from organic solvents, which are potentially cytotoxic. Dupuy, et al. (1988) have reported the microencapsulation of islets by polymerization of acrylamide to form polyacrylamide gels. However, the polymerization process requires the presence of toxic monomers such as acrylamide and cross-linkers, and, if allowed to proceed rapidly to completion, generates local heat.

40 **[0007]** Microcapsules formed by the coacervation of alginate and poly(L-lysine) have been shown to be immunoprotective, for example, as described by O'Shea, et al., 1986. However, a severe fibrous overgrowth of these microcapsules was observed following implantation (McMahon, et al. 1990; O'Shea, et al., 1986). The use of poly(ethylene oxide) (PEO) to increase biocompatibility is well documented in literature. The biocompatibility of algin-*poly*(L-lysine) microcapsules has been reported to be significantly enhanced by incorporating a graft copolymer of PLL and PEO on the 45 microcapsule surface (Sawhney, et al., "Poly(ethylene oxide)-Graft-Poly(L-Lysine) Copolymers to Enhance the Biocompatibility of Poly(L-Lysine)-Alginate Microcapsule Membranes,"

(1991) *Biomaterials*, 13, 863-870).

50 **[0008]** The PEO chain is highly water soluble and highly flexible. PEO chains have an extremely high motility in water and are essentially non-ionic in structure. Immobilization of PEO on a surface has been largely carried out by the synthesis of graft copolymers having PEO side chains (Sawhney, et al.; Miyama, et al., 1988; Nagoaka, et al.). This process involves the custom synthesis of monomers and polymers for each application. The use of graft copolymers, however, still does not guarantee that the surface "seen" by a macromolecule consists entirely of PEO.

55 **[0009]** Electron beam cross-linking has been used to synthesize PEO hydrogels, which have been reported to be non-thrombogenic by Sun, et al., (1987) *Polymer Prepr.*, 28:292-294; Dennison, K.A., (1986) Ph.D. Thesis. Massachusetts Institute of Technology. However, use of an electron beam precludes including with the polymer any living tissue since the radiation is cytotoxic. Also, the networks produced by this method are difficult to characterize due to

the non-specific cross-linking induced by the electron beam.

[0010] Photopolymerization of PEG diacrylates in the presence of short wavelength ultraviolet light initiation has been used to entrap yeast cells for fermentation and chemical conversion (Kimura, et al. (1981), "Some properties of immobilized glycolysis system of yeast in fermentative phosphorylation of nucleotides," *Eur. J. Appl. Microbio. Biotechnol.*, 11:78-80; Omata *et al.*, (1981), "Steroselective hydrolysis of dl-methyl succinate by gel-entrapped Rhodotorula minuta uvr. texensis cells in organic solvent," *Eur. J. Appl. Microbial Biotechnol.*, 11:199-204; Okada, T., *et al.*, "Application of Entrapped Growing Yeast Cells to Peptide Secretion System," *Appl. Microbiol. Biotechnol.*, Vol. 26, pp. 112-116 (1987). Other methods for encapsulation of cells within materials photopolymerizable with short wavelength ultraviolet radiation have been used with microbial cells (Kimura, *et al.*, 1981; Omata, *et al.*, 981; Okada, *et al.*, 1987; Tanaka, *et al.*, 1977; Omata, *et al.*, 1979a; Omata, *et al.*, 1979b; Chun, *et al.*, 1981; Fukui, *et al.*, 1976; Fukui, *et al.*, 1984). However, yeast cells and some microbial cells are much hardier and resistant to adverse environments, elevated temperatures, and short wavelength ultraviolet radiation than mammalian cells and human tissues.

[0011] United States Patent No. 4,298,002 relates to a synthetic, hydrophilic, polymeric material for encapsulating biologically active tissue. The hydrophilic material is insoluble in water and the biologically active tissue is either injected into a preformed chamber of the polymeric material or it is dispersed in the polymeric material which is subsequently polymerised.

[0012] There are several problems with these methods, including the use of methods and/or materials which are thrombogenic or unstable *in vivo*, or require polymerization conditions which tend to destroy living mammalian tissue or biologically active molecules, for example, short wavelength ultraviolet radiation. In order to encapsulate living tissue for implantation in a human or other mammalian subject, the polymerization conditions must not destroy the living tissue, and the resulting polymer-coated cells must be biocompatible.

[0013] There is also a need to encapsulate materials within a very thin layer of material that is permeable to nutrients and gases, yet strong and non-immunogenic. For example, for transplantation of islets of Langerhans, the islets, which have a diameter of 100 to 200 microns, have in the past been encapsulated within microspheres that have a diameter of 400 to 1000 microns. This large diameter can result in slowed diffusion of nutritional molecules and large transplantation volumes.

[0014] In summary, there is a need for materials, and methods of use thereof, which can be used to encapsulate cells and tissues or biologically active molecules which are biocompatible, do not elicit specific or non-specific immune responses, and which can be polymerized in contact with living cells or tissue without injuring or killing the cells, within a very short time frame, and in a very thin layer. An important aspect of the use of these materials *in vivo* is that they must be polymerizable within the time of a short surgical procedure or before the material to be encapsulated disperses, is damaged or dies.

[0015] It is therefore an object of the present invention to provide a polymeric material that can be polymerized in contact with living cells and tissues, and in a very short time period.

[0016] It is a further object of the present invention to provide a polymeric material which is biocompatible and resistant to degradation for a specific time period.

[0017] It is a still further object of the present invention to provide a polymeric material which is permeable to nutrients and gases yet can protect cells and tissues from *in vivo* attack by other cells.

Summary of the Invention

[0018] Disclosed herein is a method for polymerization of macromers using visible or long wavelength ultraviolet light (lw uv light, 320 nm or greater) to encapsulate or coat either directly or indirectly living tissue with polymeric coatings which conform to the surfaces of cells, tissues or carriers thereof under rapid and mild polymerization conditions. Aspects of the invention are defined in the appended Claims 1, 2, 31, 32, 33 and 34. Polymers are formed from non-toxic pre-polymers, referred to herein as macromers, that are water-soluble or substantially water soluble and too large to diffuse into the cells to be coated. Examples of macromers include highly biocompatible PEG hydrogels, which can be rapidly formed in the presence or absence of oxygen, without use of toxic polymerization initiators, at room or physiological temperatures, and at physiological pH. Polymerization may be initiated using non-toxic dyes such as methylene blue or eosin Y, which are photopolymerizable with visible or lw uv light. Other dyes that diffuse into the cells but are nontoxic, such as ethyl eosin, may also be used. The process is non-cytotoxic because little light is absorbed by cells in the absence of the proper chromophore. Cells are largely transparent to this light, as opposed to short wavelength UV radiation, which is strongly absorbed by cellular proteins and nucleic acids and can be cytotoxic. Low levels of irradiation (5-500 mW) are usually enough to induce polymerization in a time period of between milliseconds to a few seconds for most macromers. A second reason for the lack of cytotoxicity is that the polymerizable species does not diffuse into cells.

[0019] The resulting polymers can act as semipermeable membranes, as adhesives as tissue supports, as plugs, as barriers to prevent the interaction of one cell tissue with another cell or tissue, and as carriers for bioactive species.

A wide variety of surfaces, with different geometries, can be coated with a three dimensionally cross-linked network of these polymeric materials. The polymers can be formed into a matrix for delivery of biologically active materials, including proteins, polysaccharides, organic compounds with drug activity, and nucleic acids.

[0020] In one preferred embodiment, the polymer is used to form a layer on the inside of the lumen of a blood vessel, either for structural support, prevention of thrombosis and inflammatory reactions at the lumen surface, and/or delivery of therapeutic agents to the blood vessel. In another preferred embodiment, the polymer is used to create a semipermeable barrier around cells such as islets of Langerhans to protect the cell by preventing the passage of immunoglobulins molecules or cells, while allowing free transfer of nutrients, gases and small cell products. Such treated islets may be useful in treating diseases which result from deficiencies in metabolic processing, or diseases like diabetes which arise from insufficient concentrations of bioregulator molecules.

Brief Description of the Drawings

[0021]

Figure 1 is a reaction scheme for ethyl eosin initiated polymerization.
 Figure 2A is a schematic of dye-initiated polymerization of a PEG layer around crosslinked alginate microspheres.
 Figure 2B is a photomicrograph of the alginate/poly(L-lysine) microspheres containing human islets of Langerhans coated with a PEG 18.5K tetraacrylate hydrogel using the dye binding method depicted in Figure 2A.

 Figure 7B is a photomicrograph of Alginate-PLL microspheres coated with a PEG 18.5K Da tetraacrylate, using the dye diffusion method depicted in Figure 1.
 Figures 8A-F is a graph of the number of cells versus gel composition, for the unattached cells obtained from lavage of the peritoneal cavity in mice with different PEO overcoat gel compositions: a - 18.5k; b - 10% 0.5k, 90% 18.5k; c - 50% 18.5k, 50% 0.4k; d - 10% 0.4k, 90% 35k; e - 50% 0.4k, 50% 35k; and f - alginate-poly(L-lysine) control.
 Figure 9 is a graph of the % protein released versus time in minutes, for diffusion of bovine serum albumin (open squares), human IgG (triangles) and human fibrinogen (closed squares) through a PEO 18.5K-tetraacrylate gel.
 Figure 10 is a graph of the % diffusion of bovine serum albumin over time in minutes through PEO 400 diacrylate (open squares) and PEG 18.5K-tetracrylate (triangles) gels.
 Figure 11A is a graph of the length in mm of gel produced by argon ion laser induced polymerization versus log (time) (ms) of trimethylolpropane using an amine and ethyl eosin initiation system.
 Figure 11B is a photomicrograph of the spikes formed as a result of laser irradiation of ethoxylated trimethylol propane triacrylate for durations of 67 ms, 125 ms, 250 ms, 500 ms, and 1 set.
 Figure 12A is a photomicrograph of human foreskin fibroblasts cultured for 6 h on a glass coverslip coated with PEG 18.5K-tetraacrylate gel.
 Figure 12B is a photomicrograph of human foreskin fibroblasts cultured for 6 h on a glass that was not coated with PEG.
 Figure 13 is a photomicrograph of PEG 18.5K-tetraacrylate microspherical gels, implanted in mice, and explanted after 4 days, showing very little fibrous overgrowth.

Detailed Description of the Invention

[0022] As described herein, biocompatible polymeric materials are formed for use in juxtaposition with biologically active materials or cells and tissue, by free radical polymerization of biocompatible water soluble macromers including at least two polymerizable substituents. These polymeric coating materials can be either homopolymers, copolymers or block' copolymers. As used herein, a polymer is a unit formed having a degree of polymerization greater than 10, and an oligomer has a degree of polymerization of between 2 and 10, degree of polymerization meaning the number of repeat units in the structure, e.g., d.p. = 3 refers to a trimer. Polymerization of a component that has at least two

polymerizable substituents is equal to gelation; the polymerization proceeds to form a three-dimensional, cross-linked gel.

Pre-polymers (Macromers) useful for Making Gels.

5

[0023] The general criteria for pre-polymers (referred to herein as macromers) that can be polymerized in contact with biological materials or cells are that: they are water-soluble or substantially water soluble, they can be further polymerized or crosslinked by free radical polymerization, they are non-toxic and they are too large to diffuse into cells, i.e., greater than 200 molecular weight. Substantially water soluble is defined herein as being soluble in a mixture of water and organic solvent(s), where water makes up the majority of the mixture of solvents.

10

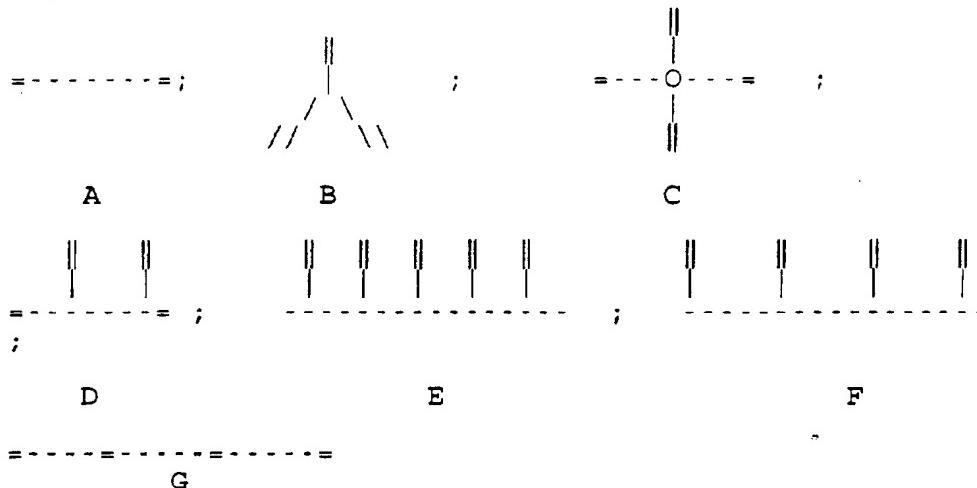

[0024] As used herein, the macromers must be photopolymerizable with light alone or in the presence of an initiator and/or catalyst, such as a free radical photoinitiator, wherein the light is in the visible or long wavelength ultraviolet range, that is, greater than or equal to 320 nm. Other reactive conditions may be suitable to initiate free radical polymerization if they do not adversely affect the viability of the living tissue to be encapsulated. The macromers must also not generate products or heat levels that are toxic to living tissue during polymerization. The catalyst or free radical initiator must also not be toxic under the conditions of use.

15

[0025] A wide variety of substantially water soluble polymers exist, some of which are illustrated schematically below. (—) represents a substantially water soluble region of the polymer, and (=) represents a free radical polymerizable species. Examples include:

20

25

30

35

40

[0026] Examples of A include PEG diacrylate, from a PEG diol; of B include PEG triacrylate, formed from a PEG triol; of C include PEG-cyclodextrin tetraacrylate, formed by grafting PEG to a cyclodextrin central ring, and further acrylating; of D include PEG tetraacrylate, formed by grafting two PEG diols to a bis epoxide and further acrylating; of E include hyaluronic acid methacrylate, formed by acrylating many sites on a hyaluronic acid chain; of F include PEG-hyaluronic acid-multiacrylate, formed by grafting PEG to hyaluronic acid and further acrylating; of G include PEG-unsaturated diacid ester formed by esterifying a PEG diol with an unsaturated diacid.

45

[0027] Polysaccharides include, for example, alginate, hyaluronic acid, chondroitin sulfate, dextran, dextran sulfate, heparin, heparin sulfate, heparan sulfate, chitosan, gellan gum, xanthan gum, guar gum, and K-carrageenan. Proteins, for example, include gelatin, collagen, elastin and albumin, whether produced from natural or recombinant sources.

50

[0028] Photopolymerizable substituents preferably include acrylates, diacrylates, oligoacrylates, dimethacrylates, or oligomethacrylates, and other biologically acceptable photopolymerizable groups.

Synthetic Polymeric Macromers.

55

[0029] The water-soluble macromer may be derived from water-soluble polymers including, but not limited to, poly(ethylene oxide) (PEO), poly(ethylene glycol) (PEG), poly(vinyl alcohol) (PVA), poly(vinylpyrrolidone) (PVP), poly(ethylloxazoline) (PEOX) polyaminoacids, pseudopolyamino acids, and polyethylloxazoline, as well as copolymers of these with each other or other water soluble polymers or water insoluble polymers, provided that the conjugate is water

soluble. An example of a water soluble conjugate is a block copolymer of polyethylene glycol and polypropylene oxide, commercially available as a Pluronic™ surfactant.

Polysaccharide Macromers

5

[0030] Polysaccharides such as alginate, hyaluronic acid, chondroitin sulfate, dextran, dextran sulfate, heparin, heparin sulfate, heparan sulfate, chitosan, gellan gum, xanthan gum, guar gum, water soluble cellulose derivatives, and carrageenan, which are linked by reaction with hydroxyls or amines on the polysaccharides can also be used to form the macromer solution.

10

Protein Macromers

[0031] Proteins such as gelatin, collagen, elastin, zein, and albumin, whether produced from natural or recombinant sources, which are made free-radical polymerization by the addition of carbon-carbon double or triple bond-containing moieties, including acrylate, diacrylate, methacrylate, ethacrylate, 2-phenyl acrylate, 2-chloro acrylate, 2-bromo acrylate, itaconate, oligoacrylate, dimethacrylate, oligomethacrylate, acrylamide, methacrylamide, styrene groups, and other biologically acceptable photopolymerizable groups, can also be used to form the macromer solution.

Dye-sensitized Polymerization

20

[0032] Dye-sensitized polymerization is well known in the chemical literature. For example, light from an argon ion laser (514 nm), in the presence of an xanthin dye and an electron donor, such as triethanolamine, to catalyze initiation, serves to induce a free radical polymerization of the acrylic groups in a reaction mixture (Neckers, *et al.*, (1989) *Polym. Materials Sci. Eng.*, 60:15; Fouassier, *et al.*, (1991) *Makromol. Chem.*, 192:245-260). After absorbing the laser light, the dye is excited to a triplet state. The triplet state reacts with a tertiary amine such as the triethanolamine, producing a free radical which initiates the polymerization reaction. Polymerization is extremely rapid and is dependent on the functionality of the macromer and its concentration, light intensity, and the concentration of dye and amine.

Photoinitiating Dyes

30

[0033] Any dye can be used which absorbs light having a frequency between 320 nm and 900 nm, can form free radicals, is at least partially water soluble, and is non-toxic to the biological material at the concentration used for polymerization. There are a large number of photosensitive dyes that can be used to optically initiate polymerization, such as ethyl eosin, eosin Y, fluorescein, 2,2-dimethoxy-2-phenyl acetophenone, 2-methoxy,2-phenylacetophenone, camphorquinone, rose bengal, methylene blue, erythrosin, phloxime, thionine, riboflavin, methylene green, acridine orange, xanthine dye, and thioxanthine dyes.

[0034] The preferred initiator dye is ethyle eosin due to its spectral properties in aqueous solution (absorption max = 528 nm, extinction coefficient = $1.1 \times 10^5 \text{ M}^{-1}\text{cm}^{-1}$, fluorescence max = 547 nm, quantum yield = 0.59). A reaction scheme using ethyl eosin is shown in Figure 1 as an example. The dye bleaches after illumination and reaction with amine into a colorless product, allowing further beam penetration into the reaction system.

Cocatalyst.

[0035] The cacatalysts useful with the photoinitiating dyes are nitrogen based compounds capable of stimulating the free radical reaction. Primary, secondary, tertiary or quaternary amines are suitable cocatalysts, as are any nitrogen atom containing electron-rich molecules. Cocatalysts include, but are not limited to, triethanolamine, triethylamine, ethanolamine, N-methyl diethanolamine, N,N-dimethyl benzylamine, dibenzyl amine, N-benzyl ethanolamine, N-isopropyl benzylamine, tetramethyl ethylenediamine, potassium persulfate, tetramethyl ethylenediamine, lysine, ornithine, histidine and arginine.

[0036] Examples of the dye/photoinitiator system includes ethyl eosin with an amine, eosin Y with an amine, 2,2-dimethoxy-2-phenoxyacetophenone, 2-methoxy-2-phenoxyacetophenone, camphorquinone with an amine, and rose bengal with an amine.

[0037] In some cases, the dye may absorb light and initiate polymerization, without any additional initiator such as the amine. In these cases, only the dye and the macromer need be present to initiate polymerization upon exposure to light. The generation of free radicals is terminated when the laser light is removed. Some photoinitiators, such as 2,2-dimethoxy-2-phenylacetophenone, do not require any auxiliary amine to induce photopolymerization; in these cases, only the presence of dye, macromer, and appropriate wavelength light is required.

Means for Polymerization.**Photopolymerization.**

[0038] Preferred light sources include various lamps and lasers such as those described in the following examples, which have a wavelength of about 320-800 nm, most preferably about 365 nm or 514 nm.

[0039] This light can be provided by any appropriate source able to generate the desired radiation, such as a mercury lamp, longwave UV lamp, He-Ne laser, or an argon ion laser, or through the use of fiber optics.

Other Means for Polymerization.

[0040] Means other than light can be used for polymerization. Examples include initiation by thermal initiators, which form free radicals at moderate temperatures, such as benzoyl peroxide, with or without triethanolamine, potassium persulfate, with or without tetramethylethylenediamine, and ammonium persulfate with sodium bisulfite.

Incorporation of Biologically Active Materials.

[0041] The water soluble macromers can be polymerized around biologically active molecules to form a delivery system for the molecules or polymerized around cells, tissues, sub-cellular organelles or other sub-cellular components to encapsulate the biological material. The water soluble macromers can also be polymerized to incorporate biologically active molecules to impart additional properties to the polymer, such as resistance to bacterial growth or decrease in inflammatory response, as well as to encapsulate tissues. A wide variety of biologically active material can be encapsulated or incorporated, including proteins, peptides, polysaccharides, organic or inorganic drugs, nucleic acids, sugars, cells, and tissues.

[0042] Examples of cells which can be encapsulated include primary cultures as well as established cell lines, including transformed cells. These include but are not limited to pancreatic islet cells, human foreskin fibroblasts, Chinese hamster ovary cells, beta cell insulomas, lymphoblastic leukemia cells, mouse 3T3 fibroblasts, dopamine secreting ventral mesencephalon cells, neuroblastoid cells, adrenal medulla cells, and T-cells. As can be seen from this partial list, cells of all types, including dermal, neural, blood, organ, muscle, glandular, and immune system cells, as well as species of origin, can be encapsulated successfully by this method. Examples of proteins which can be encapsulated include hemoglobin, enzymes such as adenosine deaminase, enzyme systems, blood clotting factors, inhibitors or clot dissolving agents such as streptokinase and tissue plasminogen activator, antigens for immunization, and hormones, polysaccharides such as heparin, oligonucleotides such as antisense, bacteria and other microbial organisms, including viruses, vitamins, cofactors, and retroviruses for gene therapy can be encapsulated by these techniques.

[0043] The biological material can be first enclosed in a structure such as a polysaccharide gel. (Lim, U.S.P.N. 4,352,883; Lim, U.S.P.N. 4,391,909; Lim, U.S.P.N. 4,409,331; Tsang, et al., U.S.P.N. 4,663,286; Goosen et al., U.S.P. N. 4,673,556; Goosen et al., U.S.P.N. 4,689,293; Goosen et al., U.S.P.N. 4,806,355; Rha et al., U.S.P.N. 4,744,933; Rha et al., U.S.P.N. 4,749,620.) Such gels can provide additional structural protection to the material, as well as a secondary level of perm-selectivity.

Polymerization.

[0044] The macromers are preferably mixed with initiator, applied to the material or site where they are to be polymerized, and exposed to initiating agent, such as light or heat.

[0045] In a preferred method, a photo-initiating system is added to an aqueous solution of a photopolymerizable macromer to form an aqueous mixture; the biologically active material is added; and the aqueous solution irradiated with light. The macromer is preferably formed of a water soluble polymer with photopolymerizable substituents. Light absorption by the dye/initiator system results in the formation of free radicals which initiate polymerization.

[0046] In a second preferred method, macromer is coated on the surface of a three-dimensional object which may be of biological origin or a synthetic substrate for implantation in an animal. Water-soluble macromer is mixed with a photoinitiating system to form an aqueous mixture; the mixture is applied to a surface to be coated to form a coated surface; and the coated surface is irradiated with light to initiate macromer polymerization.

[0047] In a variation of this embodiment, the synthetic substrate can be a hydrophilic microsphere, microcapsule or bead. The hydrophilic microspheres are mixed with a water soluble macromer solution in combination with a photoinitiator system to form an aqueous mixture; the microspheres are suspended with agitation with macromer in oil to form an oil suspension, and the microspheres are irradiated with light.

[0048] In another particularly preferred embodiment, a photosensitive dye is absorbed to a tissue surface which is to be treated, the non-absorbed dye is diluted out or rinsed off the tissue, the macromer solution is applied to the dye-

coupled surface, and polymerization initiated, to result in interfacial polymerization.

[0049] Polymerization can be effected by at least five different methods utilizing bulk polymerization or interfacial polymerization. These embodiments are further described below with respect to specific applications of the materials and processes for polymerization thereof.

5

Bulk Polymerization.

[0050] In bulk polymerization the material to be coated is placed in contact with a solution of macromer, photoinitiator and optionally cocatalyst, and then polymerization induced, for example, by exposure to radiation. Three examples of bulk polymerization follow:

10

Bulk Suspension Polymerization Method for Encapsulation of material.

[0051] Biological material to be encapsulated is mixed with an aqueous macromer solution, including macromer, cocatalyst and optionally an accelerator, and initiator. Small globular geometric structures such as spheres, ovoids, or oblongs are formed, preferably either by coextrusion of the aqueous solution with air or with a non-miscible substance such as oil, preferably mineral oil, or by agitation of the aqueous phase in contact with a non-miscible phase such as an oil phase to form small droplets. The macromer in the globules is then polymerized by exposure to radiation. Because the macromer and initiator are confined to the globules, the structure resulting from polymerization is a capsule in which the biological material is enclosed. This is a "suspension polymerization" whereby the entire aqueous portion of the globule polymerizes to form a thick membrane around the cellular material.

20

Microcapsule Suspension Polymerization Method.

[0052] In a variation of the bulk suspension method, microencapsulated material is used as a core about which the macromer is polymerized in a suspension polymerization reaction. The biological material is first encapsulated within a microsphere, microcapsule, or microparticle (referred to herein collectively as microcapsules), for example, in alginate microcapsules. The microcapsules are then mixed with the macromer solution and initiator, and the macromer solution polymerized.

25

[0053] This method is particularly suitable for use with PEG macromers, taking advantage of the extreme hydrophilicity of PEG macromers, and is especially well adapted for use with hydrogel microcapsules such as alginate-poly(L-lysine). The microsphere is swollen in water. When a macromer solution containing catalyst and/or initiator or accelerator is forced to phase separate in a hydrophobic medium, such as mineral oil, the PEG macromer solution prefers to stay on the hydrophilic surface of the alginate microcapsule. When this suspension is irradiated, the PEG macromer undergoes polymerization and gelation, forming a thin layer of polymeric, water insoluble gel around the microsphere.

30

[0054] This technique preferably involves coextrusion of the microcapsule in a solution of macromer and initiator, the solution being in contact with air or a liquid which is non-miscible with water, to form droplets which fall into a solution such as mineral oil in which the droplets are not miscible. The non-miscible liquid is chosen for its ability to maintain droplet formation. Additionally, if the membrane-encapsulated material is to be injected or implanted in an animal, any residue should be non-toxic and non-immunogenic. Mineral oil is a preferred non-miscible liquid. Once the droplets have contacted the non-miscible liquid, they are polymerized.

35

[0055] This coextrusion technique results in a crosslinked polymer coat of greater than 50 microns thickness. Alternatively, the microcapsules may be suspended in a solution of macromer and initiator which is agitated in contact with a non-miscible phase such as an oil phase. The resulting emulsion is polymerized to form a polymer coat, also of greater than 50 microns thickness, around the microcapsules.

40

Bulk Polymerization Method for Tissue Adhesion.

[0056] The polymeric material can also be used to adhere tissue. A water soluble polymerizable macromer in combination with a photoinitiator is applied to a tissue surface to which tissue adhesion is desired; the tissue surface is contacted with the tissue with which adhesion is desired, forming a tissue junction; and the tissue junction is irradiated with light until the macromers are polymerized. In the preferred embodiment, this is accomplished in seconds up to minutes, most preferably seconds.

45

[0057] In the preferred embodiment, the macromer mixture is an aqueous solution, such as that of PEG 400 diacrylate or PEG 18.5K tetraacrylate. When this solution contacts tissue which has a moist layer of mucous or fluid covering it, it intermixes with the moisture on the tissue. The mucous layer on tissue includes water soluble polysaccharides which intimately contact cellular surfaces. These, in turn, are rich in glycoproteins and proteoglycans. Thus, physical intermixing and forces of surface interlocking due to penetration into crevices, are some of the forces responsible for the

adhesion of the PEG gel to a tissue surface subsequent to crosslinking.

[0058] Specific applications for such adhesives may include blood vessel anastomosis, soft tissue reconnection, drainable burn dressings, and retinal reattachment.

5 **Bulk Polymerization to form Tissue Barriers**

[0059] If the PEG gel is polymerized away from tissue, it then presents a very non-adhesive surface to cells and tissue in general, due to the highly hydrophilic nature of the material.

10 [0060] This feature can be exploited to form barriers upon tissues to prevent attachment of cells to the coated tissue. Examples of this application include the formation of barriers upon islets of Langerhans or upon the lumen of blood vessels to prevent thrombosis or vasospasm or vessel collapse; whether by bulk polymerization (with the polymerization initiator mixed in with the macromer) or by interfacial polymerization (with the initiator absorbed to the surface).

15 **Interfacial Polymerization.**

[0061] For interfacial polymerization, the free radical initiator is adsorbed to the surface of the material to be coated, non-adsorbed initiator is diluted out or rinsed off, using a rinsing solution or by application of the macromer solution, and the macromer solution, optionally containing a cocatalyst, is applied to the material, which is then polymerized. Two examples of interfacial polymerization follow:

20 **Microcapsule Interfacial Polymerization Method.**

[0062] Biological material can be encapsulated as described above with reference to suspension polymerization, but utilizing interfacial polymerization to form the membrane on the surface of the biological material or microcapsule.

25 This involves coating the biological material or microcapsule with photoinitiator, suspending the biological material or microcapsules in the macromer solution, and immediately polymerizing, for example, by irradiating. A thin polymer coat, of less than 50 microns thickness, is formed around the biological materials or the microcapsule, because the photoinitiator is present only at the microcapsule surface and is given insufficient time to diffuse far into the macromer solution.

30 [0063] In most cases, initiator, such as a dye, will penetrate into the interior of the biological material or the microcapsule, as well as adsorbing to the surface. When macromer solution, optionally containing a cocatalyst such as triethanolamine, is applied to the surface and exposed to an initiating agent such as laser light, all the essential components of the reaction are present only at and just inside the interface of the biological material or microcapsule and macromer solution. Hence, polymerization and gelation (if multifunctional macromer is used), which typically occurs 35 within about 100 msec, initially takes place only at the interface, just beneath it, and just beyond it. If left for longer periods of time, initiator starts diffusing from the inner core of the microsphere into the solution; similarly, macromers start diffusing inside the core and a thicker layer of polymer is formed.

40 **Direct Interfacial Polymerization Method.**

[0064] Interfacial polymerization to form a membrane directly on the surface of tissues. Tissue is directly coated with initiator, excess initiator is removed, macromer solution is applied to the tissue and polymerized.

45 **Control of Polymer Permeability.**

[0065] The permeability of the coating is determined in part by the molecular weight and crosslinking of the polymer. For example, in the case of short PEG chains between crosslinks, the "pore" produced in the network will have relatively 50 rigid boundaries and will be relatively small so that a macromolecule attempting to diffuse through this gel will be predominantly restricted by a sieving effect. If the chain length between crosslinks is long, the chain can fold and move around with a high motility so that diffusing macromolecules will encounter a free volume exclusion effect as well as a sieving effect.

[0066] Due to these two contrasting effects a straightforward relation between molecular weight cutoff for diffusion and the molecular weight of the starting oligomer is not completely definable. Yet, a desired release profile for a particular protein or a drug such as a peptide can be accomplished by adjusting the crosslink density and length of PEG segments.

55 Correspondingly, a desired protein permeability profile can be designed to permit the diffusion of nutrients, oxygen, carbon dioxide, waste products, hormones, growth factors, transport proteins, and secreted cellularly synthesized products such as proteins, while restricting the diffusion of immune modulators such as antibodies and complement proteins, as well as the ingress of cells, inside the gel, to protect transplanted cells or tissue. The three dimensional crosslinked

covalently bonded polymeric network is chemically stable for long-term *in vivo* applications.

[0067] For purposes of encapsulating cells and tissue in a manner which prevents the passage of antibodies across the membrane but allows passage of nutrients essential for cellular metabolism, the preferred starting macromer size is in the range of between 10,000 D and 18,500 D, with the most preferred being around 18,500 D. Smaller macromers result in polymer membranes of a higher density with smaller pores.

Thickness and Conformation of Polymer Layer.

[0068] Membrane thickness affects a variety of parameters, including perm-selectivity, rigidity, and size of the membrane. Thickness can be varied by selection of the reaction components and/or the reaction conditions. For example, the macromer concentration can be varied from a few percent to 100 %, depending upon the macromer. Similarly, more intense illuminations and longer illuminations will yield thicker films than less intense or shorter illuminations will. Accelerators may also be added in varying concentration to control thickness. For example, N-vinylpyrrolidinone may be added as an accelerator, with higher concentrations yielding thicker layers than lower concentrations, all other conditions being equal. As an example, N-vinylpyrrolidinone concentrations can range from 0 to 0.5 %.

[0069] In the interfacial polymerization method, the duration of the polymerization can be varied to adjust the thickness of the polymer membrane formed. This correlation between membrane thickness and duration of irradiation occurs because the photoinitiator diffuses at a steady rate, with diffusion being a continuously occurring process. Thus, the longer the duration of irradiation, the more photoinitiator will initiate polymerization in the macromer mix, the more macromer will polymerize, and the thicker the resulting membrane. Additional factors which affect membrane thickness are the number of reactive groups per macromer and the concentration of accelerators in the macromer solution. This technique allows the creation of very thin membranes because the photoinitiator is first present in a very thin layer at the surface of the biological material, and polymerization only occurs where the photoinitiator is present.

[0070] In the suspension polymerization method, a somewhat thicker membrane is formed than with the interfacial polymerization method, since in the suspension method polymerization occurs throughout the macromer solution. The thickness of membranes formed by the suspension method is determined in part by the viscosity of the macromer solution, the concentration of the macromer in that solution, the fluid mechanical environment of the suspension and surface active agents in the suspension. These membranes vary in thickness from between 50 and 300 microns.

Non-Biological Surfaces.

[0071] The macromer solution and initiator can also be applied to a non-biological surface intended to be placed in contact with a biological environment. Such surfaces include, for example, vascular grafts, contact lenses, intraocular lenses, ultrafiltration membranes, and containers for biological materials.

[0072] It is usually difficult to get good adhesion between polymers of greatly different physicochemical properties. The concept of a surface physical interpenetrating network was presented by Desai and Hubbel (N.P. Desai et al. (1992)). This approach to incorporating into the surface of one polymer a complete coating of a polymer of considerably different properties involved swelling the surface of the polymer to be modified (base polymer) in a mutual solvent, or a swelling solvent, for the base polymer and for the polymer to be incorporated (penetrant polymer). The penetrant polymer diffused into the surface of the base polymer. This interface was stabilized by rapidly precipitating or deswelling the surface by placing the base polymer in a nonsolvent bath. This resulted in entanglement of the penetrant polymer within the matrix of the base polymer at its surface in a structure that was called a surface physical interpenetrating network.

[0073] This approach can be improved upon by photopolymerizing the penetrant polymer upon the surface of the base polymer in the swollen state.

This results in much enhanced stability over that of the previous approach and in the enhancement of biological responses to these materials. The penetrant may be chemically modified to be a prepolymer macromer, i.e. capable of being polymerized itself. This polymerization can be initiated thermally or by exposure to visible, ultraviolet, infrared, gamma ray, or electron beam irradiation, or to plasma conditions. In the case of the relatively nonspecific gamma ray or electron beam radiation reaction, chemical incorporation of particularly reactive sites may not be necessary.

[0074] Polyethylene glycol (PEG) is a particularly useful penetrant polymer for biomedical applications where the lack of cell adhesion is desired. The previous work had demonstrated an optimal performance at a molecular weight of 16,500 D without chemical crosslinking. PEG prepolymers can be readily formed by acrylation of the hydroxyl groups at its termini or elsewhere within the chain. These prepolymers can be readily polymerized. Photoinitiated polymerization of these prepolymers is particularly convenient and rapid. There are a variety of visible light initiated and ultraviolet light initiated reactions that are initiated by light absorption by specific photochemically reactive dyes. This same approach can be used with other water-soluble polymers, such as poly(N-vinyl pyrrolidinone), poly(N-isopropyl acrylamide), poly(ethyl oxazoline) and many others.

Method for Formation of Polymeric Materials.

[0075] Polymeric objects are formed into a desired shape by standard techniques known to those skilled in the art, where the macromer solution, preferably containing catalyst and initiator, is shaped, then polymerized. For example, slabs may be formed by casting on a flat surface and discoidal shapes by casting into discoidal containers. Cylinders and tubes can be formed by extrusion. Spheres can be formed from emulsion oil, by co-extrusion with oil, or by co-extrusion with air, another gas or vapor. The macromer is then exposed to conditions such as light irradiation, to initiate polymerization. Such irradiation may occur subsequent to, or, when desired, simultaneously with the shaping procedures.

[0076] The macromer may also be shaped in relationship to an internal or external supporting structure. Internal supporting structures include screening networks of stable or degradable polymers or nontoxic metals. External structures include, for example, casting the gel within a cylinder so that the internal surface of the cylinder is lined with the gel containing the biological materials.

Method for Surface Coating.

[0077] These materials can be applied to the treatment of macrocapsular surfaces, such as those used for ultrafiltration, hemodialysis and non-microencapsulated immunoisolation of animal tissue. The microcapsule in this case will usually be microporous with a molecular weight cutoff below 70,000 Da. It may be in the form of a hollow fiber, a spiral module, a flat sheet or other configuration. The surface of such a microcapsule can be modified using a polymer such as PEG to produce a non-fouling, non-thrombogenic, and non-cell-adhesive surface. The coating serves to enhance biocompatibility and to offer additional immunoprotection. Materials which can be modified in this manner include polysulfones, cellulosic membranes, polycarbonates, polyamides, polyimides, polybenzimidazoles, nylons, poly(acrylonitrile-co-vinyl chloride) copolymers, polyurethanes, polystyrene, poly(styrene co-acrylonitriles), poly(vinyl chloride), and poly(ethylene terephthalate).

[0078] A variety of methods can be employed to form biocompatible overcoats, depending on the physical and chemical nature of the surface. Hydrophilic surfaces can be coated by applying a thin layer (for example, between 50 and 300 microns in thickness) of a polymerizable solution such as PEG diacrylate containing appropriate amounts of dye and amine. Hydrophobic surfaces can be first rendered hydrophilic by gas plasma discharge treatment and the resulting surface can then be similarly coated, or they may simply be treated with a surfactant before or during treatment with the PEG diacrylate solution. For example, a hydrophobic polystyrene surface could first be treated by exposure to an O₂ plasma or an N₂ plasma. This results in rendering the surface more hydrophilic by the creation of oxygen-containing or nitrogen containing surface species, respectively. These species could be further treated by reaction with a substance such as acryloyl chloride, capable of producing surface-bound free radical sensitive species. Alternatively, a hydrophobic polystyrene surface could first be treated with a surfactant, such as a poly(ethylene oxide)-poly(propylene oxide) block copolymer, which could subsequently be acrylated if desired. Such treatments would result in enhanced adhesion between the hydrophilic coating layers and the hydrophobic material being treated.

Treatment of Textured Materials and Hydrogels.

[0079] The surface of materials having a certain degree of surface texture, such as woven dacron, dacron velour, and expanded poly(tetrafluoro-ethylene) (ePTFE) membranes, can be treated with the hydrogel. Textured and macroporous surfaces allow greater adhesion of the PEG gel to the material surface, allowing the coating of relatively hydrophobic materials such as PTFE and poly(ethylene terephthalate) (PET).

[0080] Implantable materials such as enzymatic and ion sensitive electrodes, having a hydrogel (such as poly(HEMA), crosslinked poly(vinyl alcohol) and poly(vinyl pyrrolidone)), on their surface, are coated with the more biocompatible PEO gel in a manner similar to the dye adsorption and polymerization technique used for the alginate-PLL microspheres in the following examples.

Treatment of Dense Materials.

[0081] Gen coatings can be applied to the surfaces of dense (e.g., nontextured, nongel) materials such as polymers, including PET, PTFE, polycarbonates, polyamides, polysulfones, polyurethanes, polyethylene, polypropylene, polystyrene, glass, and ceramics. Hydrophobic surfaces are initially treated by a gas plasma discharge or surfactant to render the surface hydrophilic. This ensures better adhesion of the gel coating to the surface. Alternatively, coupling agents may be used to increase adhesion, as readily apparent to those skilled in the art of polymer synthesis and surface modification.

Thin Interfacially Polymerized Coatings Within Blood Vessels and Upon Other Tissues.

[0082] The methodology described above can also be used to photopolymerize very thin films of non-degradable polymer coatings with blood vessels to alter the interaction of blood platelets with the vessel wall and to deliver therapeutics such as enzymes and other proteins, polysaccharides such as hyaluronic acid, nucleic acids such as antisense and ribozymes, and other organic and inorganic drugs, using the methods described above.

[0083] The immediate effect of the polymerization of the polymer inside blood vessels is to reduce the thrombogenicity of an injured blood vessel surface. This has clear utility in improving the outcome of balloon angioplasty by reducing the thrombogenicity of the vessel and reducing the incidence of lesions created by balloon dilatation. Another effect of this modification may be to reduce smooth muscle cell hyperplasia. This is expected for two reasons. First, platelets contain a potent growth factor, platelet-derived growth factor (PDGF), thought to be involved in post-angioplasty hyperplasia. The interruption of the delivery of PDGF itself poses a pharmacological intervention, in that a "drug" that would have been delivered by the platelets would be prevented from being delivered. Thrombosis results in the generation of thrombin, which is a known smooth muscle cell mitogen. The interruption of thrombin generation and delivery to the vessel wall also poses a pharmacological intervention. Moreover, there are other growth factors soluble in plasma which are known to be smooth muscle cell mitogens. The gel layer presents a permselective barrier on the surface of the tissue, and thus the gel layer is expected to reduce hyperplasia after angioplasty. Further, the gel may reduce vasospasm by protecting the vessel from exposure to vasoconstrictors such as thrombin and may reduce the incidence of acute reclosure.

[0084] The restriction of the polymerization at an interface is a very important advantage. Disease lesions inside a blood vessel are highly irregular in shape. Thus, it is very difficult to use a preshaped object, such as a balloon, to make a form which is to contain the polymerizing material adjacent to the blood vessel.

[0085] There are several other organs where one needs to control cell interaction with tissues or to create similar barriers by bulk or interfacial polymerization. This methodology is equally applicable to the other organs, as well as to encapsulation of specific cell types or biologically active materials such as enzymes for treatment of various metabolic defects and diseases, for example, as described below.

(i) **Encapsulation of Neurotransmitter-Releasing Cells.**

[0086] Paralysis agitans, more commonly called Parkinson's disease, is characterized by a lack of the neurotransmitter dopamine within the striatum of the brain. Dopamine secreting cells such as cells from the ventral mesencephalon, from neuroblastoid cell lines or from the adrenal medulla can be encapsulated using the method and materials described herein. Cells, including genetically engineered cells, secreting a precursor for a neurotransmitter, an agonist, a derivative or a mimic of a particular neurotransmitter or analogs can also be encapsulated.

(ii) **Encapsulation of Hemoglobin for Synthetic Erythrocytes**

[0087] Hemoglobin in its free form can be encapsulated in PEG gels and retained by selection of a PEG chain length and cross-link density which prevents diffusion. The diffusion of hemoglobin from the gels may be further impeded by the use of polyhemoglobin, which is a cross-linked form of hemoglobin. The polyhemoglobin molecule is too large to diffuse from the PEG gel. Suitable encapsulation of either native or crosslinked hemoglobin may be used to manufacture synthetic erythrocytes. The entrapment of hemoglobin in small spheres of less than 5 microns in diameter of these highly biocompatible materials would lead to enhanced circulation times relative to crosslinked hemoglobin or liposome encapsulated hemoglobin.

(iii) **Entrapment of Enzymes for Correction of Metabolic Disorders and Chemotherapy.**

[0088] There are many diseases and defects which result from a deficiency in enzymes. For example, congenital deficiency of the enzyme catalase causes acatalasemia. Immobilization of catalase in PEG gel networks could provide a method of enzyme replacement to treat this disease. Entrapment of glucosidase can similarly be useful in treating Gaucher's disease. Microspherical PEG gels entrapping urease can be used in extracorporeal blood to convert urea into ammonia. Enzymes such as asparaginase can degrade amino acids needed by tumor cells. Immunogenicity of these enzymes prevents direct use for chemotherapy. Entrapment of such enzymes in immunoprotective PEG gels, however, can support successful chemotherapy. A suitable formulation can be designed for either slow release or no release of the enzyme.

(iv) **Cellular Microencapsulation for Evaluation of Anti-Human Immunodeficiency Virus Drugs *In Vivo***

[0089] HIV infected or uninfected human T-lymphoblastoid cells can be encapsulated into PEG gels as described for other cells above. These microcapsules can be implanted in a nonhuman animal and then treated with test drugs.

5 After treatment, the microcapsules can be harvested and the encapsulated cells screened for viability and functional normalcy. Survival of infected T cells indicates successful action of the drug. Lack of biocompatibility is a documented problem in this approach to drug evaluations, but the highly biocompatible gels described herein should solve this problem.

10 (v) **Polymerization of Structural Coatings within Blood Vessels and other tissue lumens.**

[0090] Just as very thin intravascular coatings can be polymerized within blood vessels, thicker layers of structural gels may also be polymerized within vessels. These may be used to reduce abrupt reclosure, to hold back vessel wall dissections, to resist vasospasm, or to reduce smooth muscle cell hyperplasia. These gels may be produced by bulk or 15 interfacial polymerization, and the thicker and higher the crosslink density of the material, the stronger the structure within the vessel wall. This procedure could be carried out upon or within many organs of the body.

[0091] The following examples are presented to describe preferred embodiments and utilities of the present invention and are not meant to limit the invention unless otherwise stated in the claims appended hereto. Taken together, the 20 examples illustrate representative demonstrations of the best mode of implementing the invention as currently understood.

Example 1: Synthesis of PEG 6K Diacrylate.

[0092] PEG acrylates of molecular weights 400 Da and 1,000 Da are commercially available from Sartomer and 25 Dajac Inc., respectively. 20 g of PEG 6K diol was dissolved in 200 ml dichloromethane in a 250 ml round bottom flask. The flask was cooled to 0°C and 1.44 ml of triethyl amine and 1.3 ml of acryloyl chloride were added with constant stirring under a dry nitrogen atmosphere. The reaction mixture was then brought to room temperature and was stirred for 12 hr under a nitrogen atmosphere. It was then filtered, and the filtrate was precipitated by adding to a large excess of hexane. The crude monomer was purified by dissolving in dichloromethane and precipitating in hexane. Yield 60%.

30 **Example 2: Synthesis of PEG 18.5 K Tetraacrylate.**

[0093] 30 g of a tetrahydroxy water soluble PEG (mol wt 18,500) (PEG 18.5k) was purchased from Polysciences, Inc.

[0094] The PEG was dried by dissolving in benzene and distilling off the water-benzene azeotrope. 59 g of PEG 35 18.5 k was dissolved in 300 ml of benzene in a 500 ml flask. To this, 3.6 ml of triethylamine and 2.2 ml of acryloyl chloride were added under nitrogen atmosphere and the reaction mixture was refluxed for 2 hours. It was then cooled and stirred overnight. The triethyl amine hydrochloride was separated by filtration and the copolymer was recovered from filtrate by precipitating in a large excess of hexane. The polymer was further purified by dissolving in methylene chloride and reprecipitating in hexane. The polymer was dried at 50°C under vacuum for 1 day. Yield 68%.

40 **Example 3: Coating of Islet-Containing Alginate-PLL Microspheres by Surface Dye Adsorption.**

[0095] The microcapsule interfacial polymerization method was used to form membrane around alginate-PLL micro-capsules containing islets. Alginate-PLL coacervated microspheres, containing one or two human pancreatic islets 45 each, were suspended in a 1.1% CaCl₂ solution and aspirated free of excess solution to obtain a dense plug of micro-spheres. A solution of ethyl eosin (0.04% w/v) was prepared in a 1.1% CaCl₂ solution. This solution was filter-sterilized by passage through a 0.45 µm filter. The plug of microspheres was suspended in 10 ml of the eosin solution for 2 min to allow uptake of the dye. The microspheres were then washed four times with fresh 1.1% CaCl₂ to remove excess dye. 50 2 ml of a solution (23% w/v) of PEG 18.5 tetraacrylate containing 100 µl of a 3.5% w/v solution of triethanolamine in hydroxyethylpiperazine ethanesulfonic acid (HEPES) buffered saline was added to 0.5 ml of these microspheres. The microspheres were exposed to argon ion laser light for 30 seconds with periodic agitation. The suspension of microspheres was uniformly scanned with the light during this period. The microspheres were then washed with calcium solution and the process was repeated in order to further stabilize the coating.

[0096] Alginate/PLL microspheres containing islets coated by this technique are shown in Figure 2B.

[0097] A static glucose stimulation test (SGS) was performed on islets encapsulated in the microspheres coated with 55 PEG gel. Data for insulin secretion in response to this challenge appears in Table 1. The islets are seen to be viable by dithizone staining. The SGS test data confirm the vitality and functionality of the islets.

TABLE 1:

| Function of Encapsulated Islet Cells SGs Glucose Concentration (mg%) | | | |
|---|---------|------------------|-----------------|
| | Initial | | Subsequent |
| | 60 | 300 | 60 |
| Insulin/Islet/hr (μ U/ml)* | | | |
| Diffusion Overcoat Method | 1.0 | 10.04 \pm 3.56 | 2.54 \pm 0.76 |
| Mineral Oil Overcoat Method | 1.0 | 10.23 \pm 3.28 | 1.02 \pm 0.78 |
| Free Islet Control | 1.0 | 3.74 \pm 1.4 | 1.9 \pm 0.17 |

* Values are mean \pm S.D., all are normalized as compared to the initial 60 mg %, after subjection to the 300 mg % glucose, the islets are resubjected to the initial dose.

[0098] PEG diacrylate macromers can be polymerized identically as the PEG tetraacrylate macromer described in this example.

Example 4: Coating Islet-Containing Alginate-PLL Microspheres Suspension Polymerization Method

[0099] This method takes advantage of the hydrophilic nature of PEG monomers. 2 ml of alginate/PLL microspheres, containing one or two human pancreatic islets each, were mixed with PEG tetraacrylate macromer solution (PEG mol wt 18.5kD, 23% solution in saline) in a 50 ml transparent centrifuge tube. Triethanolamine (0.1M) and 0.5 mM ethyl eosin were mixed with macromer solution. The excess macromer solution was decanted, 20 ml of mineral oil was added to the tube, and the reaction mixture was vortexed thoroughly for 5 minutes. Silicone oil will perform equally well in this synthesis but may have poorer adjuvant characteristics if there is any carry-over. Any other water-immiscible liquid may be used as the "oil" phase. Acceptable triethanolamine concentrations range from about 1 mM to about 100 mM. Acceptable ethyl eosin concentrations range from about .01 mM to more than 10 mM.

[0100] The beads were slightly red due to the thin coating of macromer/dye solution and were irradiated for 20-50 sec with an argon ion laser (power 50-500 mW). Bleaching of the (red) ethyl eosin color suggests completion of the reaction. The beads were then separated from the mineral oil and washed several times with saline solution. The entire procedure was carried out under sterile conditions.

[0101] A schematic representation of the macrosphere coating process in oil is shown in Figure 3. Alginate/polylysine capsules are soluble in sodium citrate at pH 12. When these coated microspheres come in contact with sodium citrate at pH 12, the inner alginate/polylysine coacervate dissolves and a PEG polymeric membrane can still be seen (crosslinked PEG gels are substantially insoluble in all solvents including water and sodium citrate at pH 12). The uncoated control microspheres dissolve completely and rapidly in the same solution.

[0102] A static glucose challenge was performed on the islets as in Example 3. Data are also shown in Table 1. The islets are viable and functional.

Example 5: Encapsulation of Islets of Langerhans

[0103] This example makes use of the direct interfacial polymerization. Islets of Langerhans isolated from a human pancreas were encapsulated in PEG tetraacrylate macromer gels. 500 islets suspended in RPMI 1640 medium containing 10% fetal bovine serum were pelleted by centrifuging at 100 g for 3 min. The pellet was resuspended in 1 ml of a 23% w/v solution of PEG 18.5K tetraacrylate macromer in HEPES buffered saline. 5 μ l of an ethyl eosin solution in vinyl pyrrolidone* (at a concentration of 0.5%) was added to this solution along with 100 μ l of a 5 M solution of triethanolamine in saline. 20 ml of a mineral oil was then added to the tube which was vigorously agitated to form a dispersion of droplets 200-500 μ m in size. This dispersion was then exposed to an argon ion laser with a power of 250 mW, emitting at 514 nm, for 30 sec. The mineral oil was then separated by allowing the microspheres to settle, and the resulting microspheres were washed twice with phosphate buffered saline (PBS), once with hexane and three times with media.

[0104] Figure 4 shows islets of Langerhans encapsulated in a PEG-tetraacrylate gel. The viability of the islets was

verified by an acridine orange and propidium iodide staining method and also by dithizone staining. In order to test functional normalcy, a SGS test was performed on these islets. The response of the encapsulated islets was compared to that of free islets maintained in culture for the same time period. All islets were maintained in culture for a week before the SGS was performed. The results are summarized in Table 2. It can be seen that the encapsulated islets secreted significantly ($p < 0.05$) higher amounts of insulin than the free islets. The PEG-tetraacrylate gel encapsulation process did not impair function of the islets and in fact helped them maintain their function in culture better than if they had not been encapsulated.

TABLE 2:

| Secretion of Insulin from Islet Cells | | | |
|--|-----------------------------|------------------|----------------|
| Islet Insulin Secretion | | | |
| | Glucose Concentration (mg%) | | |
| | 60 | 300 | 60 |
| Insulin/islet/hr (μ U/ml)* | | | |
| Free islets | 1.0 | 3.74 ± 1.40 | 1.9 ± 0.17 |
| Encapsulated Islets | 1.0 | 20.81 ± 9.36 | 2.0 ± 0.76 |

* Values are mean \pm S.D., normalized to initial basal level at 60 mg% glucose.

Example 6: Microencapsulation of Animal Cells.

[0105] PEG diacylates of different molecular weight were synthesized by a reaction of acryloyl chloride with PEG as in Example 1. A 20 to 30% solution of macromer was mixed with a cell suspension and the ethyl eosin and triethanolamine initiating system before exposing it to laser light through a coextrusion air flow apparatus shown in Figure 5. Microspheres were prepared by an air atomization process in which a stream of macromer was atomized by an annular stream of air. The air flow rate used was 1,600 cc/min and macromer flow rate was 0.5 ml/min. The droplets were allowed to fall into a petri dish containing mineral oil and were exposed to laser light for about 0.15 sec each to polymerize the microspheres and make them insoluble in water. The microspheres were separated from the oil and thoroughly washed with PBS buffer to remove unreacted macromer and residual initiator. The size and shape of the microspheres was dependent on extrusion rate (0.05 to 0.1 ml/min) and extruding capillary diameter (18 Ga to 25 Ga). The polymerization times were dependent on initiator concentration (ethyl eosin concentration (5 μ M to 0.5 mM), vinyl pyrrolidone concentration (0.0% to 0.1%), triethanolamine concentration (5 to 100 mM), laser power (10 mW to 1 W), and macromer concentration (greater than 10% w/v).

[0106] A PEG diacrylate macromer of molecular weight 400 Da was used as a 30% solution in PBS, containing 0.1 M triethanolamine as a cocatalyst and 0.5 mM ethyl eosin as a photoinitiator. Spheres prepared using this method are shown in Figure 6. The polymerizations were carried out at physiological pH in the presence of air. This is significant since radical polymerizations may be affected by the presence of oxygen, and the acrylate polymerization is still rapid enough to proceed effectively.

[0107] The process also works at lower temperatures. For cellular encapsulation, a 23% solution of PEG diacrylate was used with initiating and polymerization conditions as used in the air atomization technique. Cell viability subsequent to encapsulation was checked with the trypan blue exclusion assay. Human foreskin fibroblasts (HFF), Chinese hamster ovary cells (CHO-K1), and a beta cell insuloma line (RIN5F) were found to be viable (more than 95%) after encapsulation. A wide range of PEG diacrylate concentrations greater than 10% can be used equally effectively, as can PEG tetraacrylate macromers.

Example 7: Coating of Animal Cell-Containing Alginate-PLL Microspheres and Individual Cells by Surface Dye Adsorption.

[0108] Alginate-PLL coacervated microspheres containing animal cells were suspended in a 1.1% CaCl_2 solution and were aspirated free of excess solution to obtain a dense plug of microspheres. The plug of microspheres was suspended in 10 ml of eosin solution for 2 min to allow dye uptake. 2 ml of a solution (23% w/v) of PEG 18.5 tetraacrylate containing 100 μ l of a 3.5 w/v solution of triethanolamine in HEPES buffered saline was added to 0.5 ml of these microspheres. The microspheres were exposed to an argon ion laser for 30 seconds with periodic agitation. The suspension of microspheres was uniformly scanned with the laser during this period. The microspheres were then washed with calcium solution and the process was repeated once more in order to attain a stable coating.

[0109] In order to verify survival of cells after the overcoat process, cells in suspension without the alginate/PLL

microcapsule were exposed to similar polymerization conditions. 1 ml of lymphoblastic leukemia cells (RAJI) (5×10^5 cells) was centrifuged at 300 g for 3 min. 1 ml of a 0.04% filter sterilized ethyl eosin solution was phosphate buffered saline (PBS) is added and the pellet was resuspended. The cells were exposed to the dye for 1 min and washed twice with PBS and then pelleted. 10 μ l of triethanolamine solution (0.1 M) was added to the pellet and the tube was vortexed to resuspend the cells. 0.5 ml of PEG 18.5K tetraacrylate macromer was then mixed into this suspension and the resulting mixture exposed to an argon ion laser (514 nm, 50 mW) for 45 sec. The cells were then washed twice with 10 ml saline and once with media (RPMI 1640 with 10% FCS and 1% antibiotic, antimycotic). A thin membrane of PEG-tetraacrylate gel was observed forming around each individual cell.

[0110] No significant difference in viability was seen between the control population (93% viable) and the treated cells (95% viable) by trypan blue exclusion. An assay for cell viability and function was performed by adapting the MTT-Formazan assay for the RAJI cells. This assay indicates greater than 90% survival. Similar assays were performed with two other model cell lines. Chinese hamster ovary cells (CHO-K1) show no significant difference ($p < 0.05$) in metabolic function as evaluated by the MTT-Formazan assay. 3T3 mouse fibroblasts also show no significant reduction ($p > 0.50$) in metabolic activity.

Example 8: Coating Animal Cell Containing Alginate-PLL Microsphere Suspension Polymerization Method.

[0111] Using the method described in Example 4, RAJI cells encapsulated in alginate-PLL microspheres were coated with a PEG 18.5K tetraacrylate polymeric membrane. Viability of these cells was checked by trypan blue exclusion and found to be more than 95% viable.

Example 9: Coating of Individual Islets of Langerhans by Surface Dye Adsorption.

[0112] Using the method described in Example 7, ethyl eosin was adsorbed to the surfaces of islets, a solution of the PEG macromer with triethanolamine was applied to the dye-coated cells, and the cells were exposed to light from an argon-ion laser to form a thick PEG polymeric membrane on the surface of the islets. Islet viability was demonstrated by lack of staining with propidium iodide.

Example 10: Biocompatibility of PEG on Microspheres.

[0113] *In vivo* evaluation of the extent of inflammatory response to microspheres prepared in Examples 7 and 8 was carried out by implantation in the peritoneal cavity of mice. Approximately 0.5 ml of microspheres were suspended in 5 ml of sterile HEPES buffered saline. 2.5 ml of this suspension was injected into the peritoneal cavity of ICR male swiss white mice. The microspheres were recovered after 4 days by lavage of the peritoneal cavity with 5 ml of 10U heparin/ml PBS. The extent of cellular growth on the microspheres was visually inspected under a phase contrast microscope. The number of unattached cells present in the recovered lavage fluid was counted using a Coulter counter.

[0114] Figure 7A shows a photograph of alginate-poly(L-lysine) microspheres recovered after 4 days, while Figure 7B shows similar spheres which had been coated with PEG gel by the dye diffusion process before implantation. As expected, bilayer alginate-polylysine capsules not containing an outer alginate layer were completely covered with cells due to the highly cell adhesive nature of the PLL surface, whereas the PEG coated microspheres were virtually free of adherent cells. Almost complete coverage of alginate-poly(L-lysine) was expected because polylysine has amino groups on the surface, and positively charged surface amines can interact with cell surface proteoglycans and support cell growth (Reuveny, *et al.*, (1983) *Biotechnol. Bioeng.*, 25:469-480). The photographs in Figure 7B strongly indicate that the highly charged and cell adhesive surface of PLL is covered by a stable layer of PEG gel. The integrity of the gel did not appear to be compromised.

[0115] The non-cell-adhesive tendency of these microspheres was evaluated as a percentage of the total microsphere area which appears covered with cellular overgrowth. These results are summarized in Table 3.

TABLE 3:

| Microsphere Coverage with Cell Overgrowth Following Implantation Intraperitoneally for 4 Days. | |
|---|------------------------|
| Composition of PEG gel | % Cell coverage |
| 18.5K | <1 |
| 18.5k 90%: 0.4k 10% | <1 |

TABLE 3: (continued)

| Microsphere Coverage with Cell Overgrowth Following Implantation Intraperitoneally for 4 Days. | |
|---|-----------------|
| Composition of PEG gel | % Cell coverage |
| 18.5k 50%: 0.4K 50% | <1 |
| 35k 90%: 0.4K 10% | 5-7 |
| 35k 50%: 0.4K 50% | <1 |
| Alginate-poly(L-lysine) | 60-80 |

[0116] An increase in cell count is a result of activation of resident macrophages which secrete chemical factors such as interleukins and induce nonresident macrophages to migrate to the implant site. The factors also attract fibroblasts responsible for collagen synthesis. The variation of cell counts with chemical composition of the overcoat is shown Figure 8 (A-F). It can be seen from the figure that all PEG coated spheres have substantially reduced cell counts. This is consistent with the PEG overcoat generally causing no irritation of the peritoneal cavity.

[0117] However, PEG composition does make a difference in biocompatibility, and increasing molecular weights are associated with a reduction in cell counts. This could be due to the gels made from higher molecular weight oligomers having higher potential for steric repulsion due to the longer chain lengths.

Example 11: Permeability of PEG Gels.

[0118] 20 mg of bovine serum albumin, human IgG, or human fibrinogen was dissolved in 2 ml of a 23% w/v solution of oligomeric PEG 18.5k tetraacrylate in PBS. This solution was laser polymerized to produce a gel 2 cm X 2 cm X 0.5 cm in size. The diffusion of bovine serum albumin, human IgG and human fibrinogen (mol wt 66 kDa, 150 kDa and 350 kDa respectively) was monitored through the 2 cm X 2 cm face of these gels using a total protein assay reagent (Biorad). A typical release profile for a PEG 18.5K gel was shown in Figure 9. This gel allowed a slow transport of albumin but did not allow IgG and fibrinogen to diffuse. This indicates that these gels are capable of being used as immunoprotective barriers. This is a vital requirement for a successful animal tissue microencapsulation material.

[0119] The release profile was found to be a function of crosslink density and molecular weight of the polyethylene glycol segment of the monomer. Figure 10 shows the release of bovine serum albumin (BSA) through gels made from 23% solutions of PEO diacrylates and tetraacrylates of 0.4K and 18.5K, respectively. It is evident that the 18.5K gel was freely permeable to albumin while the 0.4K gel restricted the diffusion of albumin. The release of any substance from these gels depends on the crosslink density of the network and also depends on the motility of the PEG segments in the network. This effect was also dependent upon the functionality of the macromer. For example, the permeability of a PEG 18.5K tetraacrylate gel was less than that of an otherwise similar PEG 20K diacrylate gel.

Example 12: Treatment of Silicone Rubber to form PEG gel layer to enhance biocompatibility.

[0120] 2 x 2 cm pieces of medical grade silicone rubber were soaked for 1 h in benzene containing 23% 0.4k PEG diacrylate and 0.5% 2,2-dimethoxy-2-phenyl acetophenone. The swollen rubber was irradiated for 15 min with a long wave UV lamp (365 nm). After irradiation, the sample was rinsed in benzene and dried. The air contact angles of silicone rubber under water were measured before and after treatment. The decreased contact angle of 50° after treatment, over the initial contact angle of 63° for untreated silicone rubber, reflects an increased hydrophilicity due to the presence of the PEG gel on the rubber surface.

[0121] This technique demonstrates that macromer polymerization can be used to modify a polymer surface so as to enhance biocompatibility. For instance, a polyurethane catheter can be treated by this method to obtain an implantable device coated with PEG. The PEG was firmly anchored to the surface of the polyurethane catheter because the macromer was allowed to penetrate the catheter surface (to a depth of 1-2 microns) during the soaking period before photopolymerization. Upon irradiation, an interpenetrating network of PEG and polyurethane results. The PEG was thereby inextricably intertwined with the polyurethane.

Example 13: Rate of Polymerization.

[0122] The kinetics of a typical reaction were determined to demonstrate rapidity of gelation in laser-initiated polymerizations of multifunctional acrylic monomers. Trimethylolpropyl triacrylate, containing 5×10^{-4} M ethyl eosin as a photoinitiator in 10 µmoles of N-vinyl pyrrolidone per ml of macromer mix and 0.1 M of triethanolamine as a cocatalyst,

was irradiated with a 500 mW argon ion laser (514 nm wavelength, power 3.05×10^5 W/m², beam diameter 1 mm, average gel diameter produced 1 mm). A plot of the length of the spike of gel formed by penetration of the laser beam into the gel versus laser irradiation time is shown in Figure 11A. The spikes formed as a result of laser light penetration into the macromer can be seen in Figure 11B.

[0123] 100 µl of a 23% w/w solution of various macromers in HEPES buffered saline containing 3 µl of initiator solution (300 mg/ml of 2,2 dimethoxy-2-phenoxyacetophenone in N-vinyl pyrrolidone) was placed on a glass coverslip and irradiated with a low intensity long wave UV (LWUV) lamp (Black-Ray, model 3-100A with flood). The times required for gelation to occur were noted and are given in Table 4. These times are typically in the range of 10 seconds.

TABLE 4:

| Gelling Times of Irradiated Polymer | |
|-------------------------------------|---------------------------------|
| Polymer Size | Gel Time (sec) (mean ± S.D.) |
| 0.4K | 6.9±0.5 |
| 1K | 21.3±2.4 |
| 6K | 14.2±0.5 |
| 10K | 8.3±0.2 |
| 18.5K | 6.9±0.1 |
| 20K | 9.0±0.4 |

[0124] Time periods of about 10-100 ms are sufficient to gel a 300 µm diameter droplet, a typical size of gel used in microencapsulation technology. This rapid gelation, if used in conjunction with proper choice of macromers, can lead to entrapment of living cells in a three dimensional covalently bonded polymeric network. Monochromatic laser light will not be absorbed by the cells unless a proper chromophore is present, and is considered to be harmless if the wavelength is more than about 400 nm. Exposure to long wavelength ultraviolet light, greater than 360 nm, is harmless at practical intensities and durations.

[0125] The polymerization rate of the macromer will depend on the macromer concentration, the initiator concentration, and the functionality of the macromer, e.g., the difunctionality of a PEG diacrylate or the tetrafunctionality of a PEG tetraacrylate, as well as the degree of acylation of the material.

Example 14: PEG Gel Interactions.

[0126] Biocompatibility with HFF (human foreskin fibroblasts) cells was demonstrated as follows. HFF cells were seeded on PEG 18.5K tetraacrylate gels at a density of 18,000 cells/cm² in Dulbecco's modification of Eagle's medium containing 10% fetal calf serum. The gels were then incubated at 37°C in a 5% CO₂ environment for 4 hr. At the end of this time the gels were washed with PBS to remove any non-adherent cells and were observed under a phase contrast microscope at a magnification of 200X.

[0127] Figure 12A shows the growth of these cells on a typical PEG gel as compared to a glass surface (Figure 12B). The number of attached cells/cm² was found to be 510 ± 170 on the gel surfaces as compared to $13,200 \pm 3,910$ for a control glass surface. The cells on these gels appeared rounded and were not in their normal spread morphology, strongly indicating that these gels do not encourage cell attachment.

[0128] Biocompatibility on microspheres was demonstrated as follows. Figure 13 shows a photograph of microspheres explanted from mice as in Example 10; after 4 days very little fibrous overgrowth is seen. The resistance of PEG chains to protein adsorption and hence cellular growth is well documented. Table 5 summarizes the extent of cellular overgrowth seen on these microspheres formed of various PEG diacrylate gels after implanted intraperitoneally for four days.

50

TABLE 5:

| Extent of Cellular Overgrowth on Gels PEG Diacrylate for Gels Extent of Cellular Overgrowth (mol wt, Daltons) | |
|--|--------|
| 400 | 5-10% |
| 1,000 | 15-25% |
| 5,000 | 3-5% |
| 6,000 | 2-15% |
| 10,000 | 10-20% |
| 18,500 | 4-10% |

Example 15: Characterization and Mechanical Analysis of PEG Gels.

[0129] 10 μ l of an initiator solution containing 30 mg/ml of 2,2-dimethoxy-2-phenyl acetophenone in vinyl-2-pyrrolidone was added per ml to 23% w/v solutions of PEG diacrylates (0.4K, 6K, 10K) and PEG tetraacrylates (18.5K). The solution of initiator containing macromer was placed in a 4.0 X 1.0 X 0.5 cm mold and exposed to a long wave ultraviolet lamp (365 nm) for approximately 10 seconds to induce gelation. Samples were allowed to equilibrate in phosphate buffered saline (pH 7.4) for 1 week before analysis was performed.

[0130] A series of "dogbone" samples (samples cut from a slab into the shape of a dogbone, with wide regions at both ends and a narrower long region in the middle) were cut from ultimate tensile strength tests. Thickness of the samples was defined by the thickness of the sample from which they are cut. These thicknesses ranged from approximately 0.5 mm to 1.75 mm. The samples were 20 mm long and 2 mm wide at a narrow "neck" region. The stress strain tests were run in length control at a rate of 4% per second. After each test, the cross sectional area was determined. Table 6 shows the ultimate tensile strength data. It is seen that the lower molecular weight macromers in general give stronger gels which are less extensible than those made using the higher molecular weight macromers. The PEG 18.5K tetraacrylate gel is seen to be anomalous in this series, resulting from the multifunctionality of the macromer and the corresponding higher crosslinking density in the resulting gel. This type of strengthening result could be similarly obtained with macromers obtained having other than four free radical-sensitive groups, such as acrylate groups.

TABLE 6:

| Gel Strength Tests | | | | |
|---------------------------|---|-------------|-------------|-------------|
| | PEG Acrylate Precursor Molecular Weight | | | |
| | 0.4K | 6K | 10K | 18.5K |
| Stress (kPa)* | 168+/-51 | 98+/-15 | 33+/-7 | 115+/-56 |
| % Strain* | 8+/-3 | 71+/-13 | 110+/-9 | 40+/-15 |
| Slope* | 22+/-5 | 1.32+/-0.31 | 0.27+/-0.04 | 2.67+/-0.55 |

* Values are mean+/-S.D.

[0131] For the creep tests, eight samples approximately 0.2 X 0.4 X 2 cm were loaded while submersed in saline solution. They were tested with a constant unique predetermined load for one hour and a small recovery load for ten minutes. Gels made from PEG diacrylates of 1K, 6K, and 10K, and PEG tetraacrylates of 18.5K PEG molecular weight were used for this study. The 10K test was terminated due to a limit error (the sample stretched beyond the travel of the loading frame). The 1K sample was tested with a load of 10 g and a recovery load of 0.2 g. The 6K sample was tested at a load of 13g with a recovery load of 0.5g. The 18.5K sample was tested at a load of 13g with a recovery load of 0.2 g. The choice of loads for these samples produced classical creep curves with primary and secondary regions. The traces for creep for the 1K, 6K, and 18.5K samples appear in Figure 14A-C, respectively.

Example 16: Water Content of PEG Gels.

[0132] Solutions of various macromers were made as described above. Gels in the shape of discs were made using

a mold. 400 μ l of solution was used for each disc. The solutions were irradiated for 2 minutes to ensure thorough gelation. The disc shaped gels were removed and dried under vacuum at 60°C for 2 days.

The discs were weighed (W1) and then extracted repeatedly with chloroform for 1 day. The discs were dried again and weighed (W2). The gel fraction was calculated as W2/W1. This data appears in Table 7.

[0133] Subsequent to extraction, the discs were allowed to equilibrate with HBS for 6 hours and weighed (W3) after excess water had been carefully swabbed away. The total water content was calculated as (W3-W2) X 100/W3. The data for gel water contents is summarized in the following table.

TABLE 7:

| Data for gel water contents. | | |
|------------------------------|---------------|---------------|
| Polymer Code | % Total Water | % Gel Content |
| 0.4 | - | 99.8±1.9 |
| 1K | 79.8±2.1 | 94.5±2.0 |
| 6k | 95.2±2.5 | 69.4±0.6 |
| 10k | 91.4±1.6 | 96.9±1.5 |
| 18.5k | 91.4±0.9 | 80.3±0.9 |
| 20k | 94.4±0.6 | 85.0±0.4 |

Example 17: Mechanical Stability of PEG Gels after Implantation.

[0134] PEG diacrylate (10K) and PEG tetraacrylate (mol. wt. 18.5k) were cast in dogbone shapes as described in Example 15. 23% w/w PEG-diacrylate or tetraacrylate in sterile HEPES buffered saline (HBS) (0.9% NaCl, 10 mM HEPES, pH 7.4), containing 900 ppm of 2,2-dimethoxy-2-phenoxyacetophenone as initiator, was poured into an aluminum mold and irradiated with a LWUV lamp (Black ray) for 1 min. The initial weights of these samples were found after oven-drying these gels to constant weight. The samples were Soxhlet-extracted with methylene chloride for 36 hours in order to leach out any unreacted prepolymer from the gel matrix (sol-leaching), prior to testing. The process of extraction was continued until the dried gels gave constant weight.

[0135] ICR Swiss male white mice, 6-8 weeks old (Sprague-Dawley), were anesthetized by an intraperitoneal injection of sodium pentobarbital. The abdominal region of the mouse was shaved and prepared with betadine. A ventral midline incision 10-15 mm long was made. The polymer sample, fully hydrated in sterile PBS (Phosphate buffered saline) or HEPES buffered saline (for calcification studies), was inserted through the incision and placed over the mesentery, away from the wound site. The peritoneal wall was closed with a lock stitched running suture (4.0 silk, Ethicon). The skin was closed with stainless steel skin staples, and a topical antibiotic (Furacin) was applied over the incision site. Three animals were used for each time point. One dogbone sample was implanted per mouse and explanted at the end of 1 week, 3 weeks, 6 weeks, and 8 weeks. Explanted gels were rinsed in HBS twice and then treated with 0.3 mg/ml pronase (Calbiochem) to remove any adherent cells and tissue. The samples were then oven-dried to a constant weight extracted and reswelled as mentioned before.

[0136] Tensile stress strain test was conducted on both control (unimplanted) and explanted dogbones in a small horizontal Instron-like device. The device is an aluminum platform consisting of two clamps mounted flat on a wooden board between two parallel aluminum guide. The top clamp is stationary while the bottom clamp is movable. Both the frictional surfaces of the moving clamp and the platform are coated with aluminum backed Teflon (Cole-Parmer) to minimize frictional resistance. The moving clamp is fastened to a device capable of applying a gradually increasing load. The whole set-up is placed horizontally under a dissecting microscope (Reichert) and the sample elongation is monitored using a video camera. The image from the camera is acquired by an image processor (Argus-10, Hamamatsu) and sent to a monitor. After breakage, a cross section of the break surface is cut and the area measured. The load at break is divided by this cross section to find the maximum tensile stress. Table 8 lists the stress at fracture of PEG tetraacrylate (18.5K) hydrogels explanted at various time intervals. No significant change in tensile strength is evident with time. Thus, the gels appear mechanically stable to biodegradation *in vivo* within the maximum time frame of implant in mice.

TABLE 8:

| Resistance to degradation of Polymer Implants | | |
|---|-------------------------------|------------------------------|
| TIME IMPLANTED | STRESS (KPa) (mean±error*) | STRAIN AVE. (mean±error*) |
| 1 WK | 52.8±16.7 | 0.32±0.19 |
| 3 WK | 36.7±10.6 | 0.37±0.17 |

| CONTROL | 44.9±5.3 | 0.22±0.22 |

* Error based on 90% confidence limits.

Single sample.

Example 18: Monitoring of Calcification of PEG Gels.

[0137] Disc shaped PEG-tetraacrylate hydrogels (mol. wt. 18.5k) were implanted intraperitoneally in mice as described above for a period of 1 week, 3 weeks, 6 weeks or 8 weeks. Explanted gels were rinsed in HBS twice and treated with Pronase (Calbiochem) to remove cells and cell debris. The samples were then equilibrated in HBS to let free Ca⁺⁺ diffuse out from the gel matrix. The gels were then oven-dried (Blue-M) to a constant weight and transferred to Aluminum oxide crucibles (COORS, high temperature resistant). They were incinerated in a furnace at 700°C for at least 16 hours. Crucibles were checked for total incineration, if any residual remnants or debris was seen they were additionally incinerated for 12 hours. Subsequently, the crucibles were filled with 2 ml of 0.5 M HCl to dissolve Ca⁺⁺ salt and other minerals in the sample. This solution was filtered and analyzed with atomic absorption spectroscopy (AA) for calcium content.

[0138] Calcification data on PEG-tetraacrylate (mol. wt. 18.5K) gel implants is given in Table 9. No significant increase in calcification was observed up to an 8 week period of implantation in mice.

TABLE 9:

| Calcification data on PEG-tetraacrylate (mol. wt. 18.5K) gel implants | |
|--|---|
| TIME (Days) | CALCIFICATION (mean±error*) (mg Calcium/g of Dry gel wt.) |
| 7 | 2.33 ± 0.20 |
| 21 | 0.88 ± 0.009 |
| 42 | 1.08 ± 0.30 |
| 56 | 1.17 ± 0.26 |

* Error based on 90% confidence limits.

Example 19: Use of PEG Gels as Adhesive to Rejoin Severed Nerve.

[0139] A formulation of PEG tetraacrylate (10%, 18.5K), was used as adhesive for stabilizing the sutureless apposition of the ends of transected sciatic nerves in the rat. Rats were under pentobarbital anesthesia during sterile surgical procedures. The sciatic nerve was exposed through a lateral approach by deflecting the heads of the biceps femoralis at the mid-thigh level. The sciatic nerve was mobilized for approximately 1 cm and transected with iridectomy scissors approximately 3 mm proximal to the tibial-peroneal bifurcation. The gap between the ends of the severed nerves was 2-3 mm. The wound was irrigated with saline and lightly swabbed to remove excess saline. Sterile, unpolymerized PEG tetraacrylate solution was applied to the wound. Using delicate forceps to hold the adventitia or perineurium, the nerve ends were brought into apposition, the macromer solution containing 2,2-dimethoxy-2-phenoxyacetophenone as a photoinitiator applied to the nerve ends and the wound was exposed to long wavelength UV-light (365 nm) for about 10 sec to polymerize the adhesive. The forceps were gently pulled away. Care was taken to prevent the macromer solution from flowing between the two nerve stumps. Alternatively, the nerve stump junction was shielded from illumination, e.g., with a metal foil, to prevent gelation of the macromer solution between the stumps; the remaining macromer solution was then simply washed away.

[0140] In an alternative approach, both ends of the transected nerve can be held together with one pair of forceps.

Forceps tips are coated lightly with petrolatum to prevent reaction with the adhesive.

[0141] The polymerized adhesive serves to encapsulate the wound and adhere the nerve to the underlying muscle. The anastomosis of the nerve ends resists gentle mobilization of the joint, demonstrating a moderate degree of stabilization. The muscle and skin were closed with sutures. Re-examination after one month shows that severed nerves remain reconnected, despite unrestrained activity of the animals.

Example 20: Surgical Adhesive.

[0142] Abdominal muscle flaps from female New Zealand white rabbits were excised and cut into strips 1 cm X 5 cm. The flaps were approximately 0.5 to 0.8 cm thick. The lap joint, 1 cm X 1 cm, was made using two such flaps. Two different PEO di- and tetra-acrylate macromer compositions, 0.4K (di-) and 18.5K (tetra-), were evaluated. The 0.4K composition was a viscous liquid and was used without further dilution. The 18.5K composition was used as a 23% w/w solution in HBS. 125 µl of ethyl eosin solution in n-vinyl pyrrolidone (20 mg/ml) along with 50 µl of triethanolamine was added to each ml of the adhesive solution. 100 µl of adhesive solution was applied to each of the overlapping flaps. The lap joint was then irradiated by scanning with a 2 W argon ion laser for 30 seconds from each side. The strength of the resulting joints was evaluated by measuring the force required to shear the lap joint. One end of the lap joint was clamped and an increasing load was applied to the other end, while holding the joint horizontally until it failed. Four joints were tested for each composition. The 0.4K joints had a strength of 12.0 ± 6.9 KPa (mean \pm S.D.), while the 18.5K joints had a strength of 2.7 ± 0.5 KPa. It is significant to note that it was possible to achieve photopolymerization and reasonable joint strength despite the 6-8 mm thickness of tissue. A spectrophotometric estimate using 514 nm light showed less than 1% transmission through such muscle tissue.

Example 21: Modification of polyvinyl alcohol.

[0143] 2 g of polyvinyl alcohol (mol wt 100,000-110,000) was dissolved in 20 ml of hot DMSO. The solution was cooled to room temperature and 0.2 ml of triethylamine and 0.2 ml of acryloyl chloride was added with vigorous stirring, under an argon atmosphere. The reaction mixture was heated to 70°C for 2 hr and cooled. The polymer was precipitated in acetone, redissolved in hot water and precipitated again in acetone. Finally it was dried under vacuum for 12 hr at 60°C. 5-10% w/v solution of this polymer in PBS was mixed with the UV photoinitiator and polymerized using long wavelength UV light to make microspheres 200-1,000 microns in size.

[0144] These microspheres were stable to autoclaving in water, which indicates that the gel is covalently cross-linked. The gel is extremely elastic. This macromer, PVA multiacrylate, may be used to increase the crosslinking density in PEG diacrylate gels, with corresponding changes in mechanical and permeability properties. This approach could be pursued with any number of water-soluble polymers chemically modified with photopolymerizable groups, for example with water-soluble polymers chosen from polyvinylpyrrolidone, polyethoxazoline, polyethyleneoxide-polypropylene-oxide copolymers, polysaccharides such as dextran, alginate, hyaluronic acid, chondroitin sulfate, heparin, heparin sulfate, heparan sulfate, guar gum, gellan gum, xanthan gum, carrageenan gum, and proteins, such as albumin, collagen, and gelatin.

Example 22: Use of Alternative Photopolymerizable Moieties.

[0145] Many photopolymerizable groups may be used to enable gelation. To illustrate a typical alternative synthesis, a synthesis for PEG 1K urethane methacrylate is described as follows:

[0146] In a 250 ml round bottom flask, 10 g of PEG 1K diol was dissolved in 150 ml benzene. 3.38 g of 2-isocyanoethylmethacrylate and 20 µl of dibutyltinindilaurate were slowly introduced into the flask. The reaction was refluxed for 6 hours, cooled and poured into 1000 ml hexane. The precipitate was then filtered and dried under vacuum at 60°C for 24 hours. In this case, a methacrylate free radical polymerizable group was attached to the polymer via a urethane linkage, rather than an ester link as is obtained, e.g. when reacting with aryloxyl chloride.

Example 23: Formation of Alginate-PLL-alginate Microcapsules with Photopolymerizable Polycations.

[0147] Alginate-polylysine-alginate microcapsules are made by adsorbing, or coacervating, a polycation, such as polylysine (PLL), upon a gelled microsphere of alginate. The resulting membrane is held together by charge-charge interactions and thus has limited stability. To increase this stability, the polycation can be made photopolymerizable by the addition of a carbon-carbon double bond, for example. This can be used to increase the stability of the membrane by itself, or to react, for example, with photopolymerizable PEG to enhance biocompatibility.

[0148] To illustrate the synthesis of such a photopolymerizable polycation, 1 g of polyallylamine hydrochloride was weighed in 100 ml glass beaker and dissolved in 10 ml distilled water (DW). The pH of the polymer solution was adjusted

to 7 using 0.2 M sodium hydroxide solution. The polymer was then separated by precipitating in a large excess of acetone. It was then redissolved in 10 ml DW and the solution was transferred to 50 ml round bottom flask. 0.2 ml glycidyl methacrylate was slowly introduced into the reaction flask and the reaction mixture was stirred for 48 hours at room temperature. The solution was poured into 200 ml acetone and the precipitate was separated by filtration and dried in vacuum. This macromer is useful in photochemically stabilizing an alginate-PLL-alginate, both in the presence or in the absence of a second polymerizable species such as a PEG diacrylate.

[0149] In addition to use in encapsulating cells in materials such as alginate, such photopolymerizable polycations may be useful as a primer or coupling agent to increase polymer adhesion to cells, cell aggregates, tissues and synthetic materials, by virtue of adsorption of the photopolymerizable polymer bonding to the PEG photopolymerizable gel.

Example 24: Encapsulation of Hemoglobin for Synthetic Erythrocytes.

[0150] Hemoglobin in its free form can be encapsulated in PEG gels and retained by selection of a PEG chain length and cross-link density which prevents diffusion. The diffusion of hemoglobin from the gels may be further impeded by the use of polyhemoglobin, which is a cross-linked form of hemoglobin. The polyhemoglobin molecule is too large to diffuse from the PEG gel. Suitable encapsulation of either native or crosslinked hemoglobin can be used to manufacture synthetic erythrocytes. The entrapment of hemoglobin in small spheres, less than five microns, of these highly biocompatible materials should lead to enhanced circulation times relative to crosslinked hemoglobin or liposome encapsulated hemoglobin.

[0151] Hemoglobin in PBS is mixed with the prepolymer in the following formulation:

| Hemoglobin at the desired amount | | |
|----------------------------------|-----|--|
| PEG DA (MW 10000) | 35% | |
| PEG DA (MW 1000) | 5% | |
| PBS | 60% | |

with 2,2-dimethoxy, 2-phenyl acetophenone at 1.6% of the above solution.

[0152] This solution is placed in mineral oil at a ratio of 1 part hemoglobin/prepolymer solution to 5 parts mineral oil and is rapidly agitated with a motorized mixer to form an emulsion, which is then illuminated with a long-wavelength ultraviolet light (360 nm) for 5 min to crosslink the PEG prepolymer to form a gel. The molecular weight of the prepolymer can be selected to resist the diffusion of the hemoglobin from the gel, with smaller PEG molecular weights giving less diffusion. PEG DA of molecular weight 100,000, further crosslinked with PEG DA 1000, should possess the appropriate permselectivity to restrict hemoglobin diffusion, and it should possess the appropriate biocompatibility to circulate within the bloodstream.

Example 25: Entrapment of Enzymes for Correction of Metabolic Disorders and Chemotherapy.

[0153] Congenital deficiency of the enzyme catalase causes acatalasemia. Immobilization of catalase in PEG gel networks could provide a method of enzyme replacement to treat this disease. Entrapment of glucosidase can similarly be useful in treating Gaucher's disease. Microspherical PEG gels entrapping urease can be used in extracorporeal blood to convert urea into ammonia. Enzymes such as asparaginase can degrade amino acids needed by tumor cells. Immunogenicity of these enzymes prevents direct use for chemotherapy. Entrapment of such enzymes in PEG gels, however, can support successful chemotherapy. A suitable formulation can be developed for either slow release or no release of the enzyme.

[0154] Catalase in PBS is mixed with the prepolymer in the following formulation:

| Catalase at the desired amount | | |
|--------------------------------|-----|--|
| PEG DA (MW 10000) | 35% | |
| PEG DA (MW 1000) | 5% | |
| PBS | 60% | |

with 2,2-dimethoxy, 2-phenyl acetophenone at 1.6% of the above solution.

[0155] This solution is placed in mineral oil at a ratio of 1 part catalase/prepolymer solution to 5 parts mineral oil and is rapidly agitated with a motorized mixer to form an emulsion. This emulsion is illuminated with a long-wavelength ultraviolet light (360 nm) for 5 min to crosslink the PEG prepolymer to form a gel. The mw of the prepolymer may be selected to resist the diffusion of the catalase from the gel, with smaller PEG DA molecular weights giving less diffusion.

[0156] PEG DA of MW 10,000, further crosslinked with PEG DA 1000, should possess the appropriate permselectivity to restrict catalase diffusion, and it should possess the appropriate permselectivity to permit the diffusion of hydrogen peroxide into the gel-entrapped catalase to allow the enzymatic removal of the hydrogen peroxide from the bloodstream. Furthermore, it should possess the appropriate biocompatibility to circulate within the bloodstream.

5 [0157] In this way, the gel is used for the controlled containment of a bioactive agent within the body. The active agent (enzyme) is large and is retained within the gel, and the agent upon which it acts (substrate) is small and can diffuse into the enzyme rich compartment. However, the active agent is prohibited from leaving the body or targeted body compartment because it cannot diffuse out of the gel compartment.

10 **Example 26: Cellular Microencapsulation for Evaluation of Anti-Human Immunodeficiency Virus Drugs *In Vivo*.**

[0158] HIV infected or uninfected human T-lymphoblastoid cells can be encapsulated into PEG gels as described for other cells above. These microcapsules can be implanted in a nonhuman animal to create a test system for anti-HIV drugs, and then treated with test drugs such as AZT or DDI. After treatment, the microcapsules can be harvested and 15 the encapsulated cells screened for viability and functional normalcy using a fluorescein diacetate/ethidium bromide live/dead cell assay.

Survival of infected cells indicates successful action of the drug. Lack of biocompatibility is a documented problem in this approach to drug evaluations, but can be overcome by using the gels described herein.

20

Claims

1. A non-cytotoxic method for encapsulating, sealing, plugging, or supporting a biological material or for preparing a 25 biocompatible substrate, the method comprising:

a) providing a macromer mixture by mixing

(i) a synthetic polymeric water soluble biocompatible macromer comprising at least two free radical-polymerizable substituents, wherein the macromer is non-toxic and has a molecular weight of at least 400; and
 30 (ii) a non-toxic free radical polymerization initiator selected from a visible light or a long wavelength ultraviolet light-activatable free radical initiator;

b) coating a biological material or a substrate *in vitro* with the macromer mixture, wherein the biological material is selected from the group consisting of mammalian cells, sub-cellular organelles, sub-cellular components, and aggregates of mammalian cells and the substrate is selected from microcapsules, woven matrices, porous matrices and prosthetic implants; and

c) exposing the coated biological material or coated substrate to visible or long wavelength ultraviolet light to cause polymerization of the macromers, thereby forming a polymeric gel with a degree of polymerization greater than 10.

40 2. A non-cytotoxic method for encapsulating, sealing, plugging, or supporting a biological material, the method comprising:

a) contacting a biological material with a solution of a non-toxic free-radical polymerization initiator selected from the group consisting of visible or long wavelength ultraviolet light-activatable initiators, to allow binding of the initiator to the biological material;

b) removing the unbound initiator by washing or dilution;

c) contacting the biological material *in vitro* with a water-soluble non-toxic biocompatible macromer comprising at least two free-radical polymerizable substituents, the macromer having a molecular weight of at least 400; and

d) exposing the biological material to an agent activating said initiator to cause polymerization of the macromers, thereby forming a polymeric gel with a degree of polymerization greater than 10.

55 3. The method of Claim 2 wherein the biological material is selected from the group consisting of mammalian cells, sub-cellular organelles, sub-cellular components and aggregates of mammalian cells.

4. The method of Claim 1 or 2 wherein the free-radical polymerizable substituents contain carbon-carbon double or

triple bonds.

5. The method of Claim 1 or 2 wherein the initiator is used together with a non-toxic catalyst.
- 5 6. The method of any preceding claim wherein the water soluble macromer is selected from the group consisting of poly(ethylene glycol), poly(ethylene oxide), poly(vinyl alcohol), poly(vinylpyrrolidone), poly(ethyloxazoline), or a block or random copolymer thereof comprising two or more free-radical polymerizable substituents.
- 10 7. The method of Claim 2 wherein the water soluble macromer is selected from the group consisting of poly (amino acids), polysaccharides, proteins or a block or random copolymer thereof comprising two or more free-radical polymerisable substituents.
- 15 8. The method of Claim 7 wherein the polysaccharide is selected from the group consisting of alginate, hyaluronic acid, chondroitin sulfate, dextran, dextran sulfate, heparin, heparin sulfate, heparan sulfate, chitosan, gellan gum, xanthan gum, guar gum and k-carrageenan.
9. The method of Claim 7 wherein the protein is selected from the group consisting of gelatin, collagen, albumin, zein and elastin.
- 20 10. The method of any preceding claim wherein the gel is prepared from macromers comprising an acrylate terminated poly(ethylene glycol).
- 25 11. The method of Claim 1 or 2 for encapsulating a biologically active molecule wherein the biologically active molecule is selected from the group consisting of peptides, proteins, polysaccharides, nucleic acids, organic drugs, and inorganic drugs.
- 30 12. The method of Claim 1 or 2 wherein the polymerization initiator is selected from the group consisting of an eosin dye, a substituted eosin dye, eosin Y, ethyl eosin, riboflavin, acetophenone, a substituted acetophenone, a fluorescein dye, a substituted fluorescein dye, camphorquinone, rose bengal, methylene green, methylene blue, acridine orange, erythrosin, phloximine, thionine, xanthine dyes, and thioxanthine dyes.
13. The method of Claim 5 wherein the catalyst is an amine.
- 35 14. The method of Claim 13 wherein the amine is selected from the group consisting of triethanolamine, triethylamine, ethanolamine, N-methyl diethanolamine, N,N-dimethyl benzylamine, dibenzyl amine, N-benzyl ethanolamine, N-isopropyl benzylamine, tetramethyl ethylene-diamine, lysine, ornithine, histidine and arginine.
- 40 15. The method of Claim 1 or 2 wherein polymerization is initiated by light having a wavelength of between 320 nm and 800 nm.
16. The method of Claim 15 wherein the light has a wavelength of 514 nm or 365 nm.
- 45 17. The method of Claim 3 wherein the unbound initiator is removed by dilution with the macromer solution such that polymerization occurs only at the surface of the mammalian cell, sub-cellular organelle, sub-cellular component or the mammalian cell aggregate.
18. The method of Claim 1, wherein the macromer solution is shaped and then polymerized.
- 50 19. The method of Claim 1, wherein the gel contains a supporting structure.
20. The method of Claim 1 wherein the polymer is selected and the polymerization is controlled to produce a desired permeability around the encapsulated biological material or biocompatible substrate.
- 55 21. The method of Claim 1 wherein the macromer is coated on the surface of a three-dimensioned object and the coated surface is irradiated with light to initiate macromer polymerisation.
22. The method of Claim 1, wherein a photopolymerizable polycation is pre-adsorbed to the biological material or substrate being encapsulated to increase attachment of the gel to the biological material or substrate.

23. The method of Claim 1 or 2 wherein the biological material is selected from primary or established lines of mammalian cells, sub-cellular organelles, and sub-cellular non-organelle components.
- 5 24. The method of Claim 23 wherein the cell line is selected from pancreatic islet cells, human foreskin fibroblasts, Chinese hamster ovary cells, beta cell insulomas, lymphoblastic leukemia cells, mouse 3T3 fibroblasts, dopamine secreting ventral mesencephalon cells, neuroblastoid cells, adrenal medulla cells and T-cells.
- 10 25. The method of Claim 1 wherein the biological material is first encapsulated in a microcapsule.
- 15 26. The method of Claim 25 wherein the microcapsule is comprised of ionically coagulatable or thermally coagulatable polymers which are non-toxic to the encapsulated material.
27. The method of Claim 1 wherein the macromer solution further comprises an accelerator to accelerate the rate of polymerization.
- 20 28. The method of Claim 27 wherein the accelerator comprises a small molecule containing an allyl, vinyl or acrylate group.
29. The method of Claim 28 wherein the accelerator is selected from the group consisting of N-vinyl pyrrolidinone, 2-vinyl pyridine, 1-vinyl imidazole, 9-vinyl carbazole, acrylic acid and 2-allyl, 2-methyl, 20 1-3-cyclopentane dione.
30. The method of Claim 1 wherein the macromer mixture is an aqueous solution.
31. A biological material or a biocompatible substrate obtainable by a method of Claim 1 or a biological material obtainable by a method of Claim 2 for use in medicine.
32. Use of a biological material or a biocompatible substrate obtainable by a method of Claim 1 or a biological material obtainable by a method of Claim 2 in the preparation of a medicament for use in the treatment of metabolic defects or diseases.
- 35 33. Use of a macromer mixture as claimed in anyone of Claims 1, 2, 4 to 16, 18 to 20, 22 and 27 to 30 in the manufacture of a medicament for the treatment of metabolic defects or diseases.
34. Use of a macromer mixture as claimed in any one of Claims 1, 2, 4 to 16, 18 to 20, 22 or 27 to 30 in the manufacture of a medicament for use as adhesives, as tissue supports or as plugs, or as barriers to prevent the interaction of one cell tissue with another cell or tissue.

40 **Patentansprüche**

- 41 1. Nicht-zytotoxisches Verfahren zur Verkapselung, Versiegelung, Füllung oder Stützung eines biologischen Materials oder zur Herstellung eines biokompatiblen Trägermaterials, wobei das Verfahren umfasst:
- 45 a) Bereitstellen einer Makromermischung durch das Mischen
- (i) eines synthetischen, polymeren, wasserlöslichen, biokompatiblen Makromers, das wenigstens zwei über freie Radikale polymerisierbare Substituenten aufweist, wobei das Makromer nicht-toxisch ist und ein Molekulargewicht von wenigstens 400 hat; und
- 50 (ii) eines nicht-toxischen Initiators einer über freie Radikale verlaufenden Polymerisation, der aus einem durch sichtbares Licht aktivierbaren und einem durch langwelliges ultraviolettes Licht aktivierbaren Initiator ausgewählt ist;
- 55 b) Beschichten eines biologischen Materials oder eines Trägermaterials in vitro mit der Makromermischung, wobei das biologische Material aus der Gruppe ausgewählt ist, die aus Säugetierzellen, subzellulären Organellen, subzellulären Komponenten und Aggregaten von Säugetierzellen besteht, und das Trägermaterial ausgewählt ist aus Mikrokapseln, gewebten Matrices, porösen Matrices und prothetischen Implantaten; und
- c) Exponieren des beschichteten biologischen Materials oder des beschichteten Trägermaterials gegen sichtbares oder langwelliges ultraviolettes Licht, um eine Polymerisation der Makromere zu bewirken, wodurch ein

Polymergel mit einem Polymerisationsgrad von über 10 gebildet wird.

2. Nicht-zytotoxisches Verfahren zur Verkapselung, Versiegelung, Füllung oder Stützung eines biologischen Materials oder zur Herstellung eines biokompatiblen Trägermaterials, wobei das Verfahren umfasst:

5 a) Inkontaktbringen eines biologischen Materials mit einer Lösung eines nicht-toxischen Initiators einer über freie Radikale verlaufenden Polymerisation, der aus der Gruppe ausgewählt ist, die aus Initiatoren besteht, die durch sichtbares oder langwelliges ultraviolettes Licht aktivierbar sind, um die Bindung des Initiators an das biologische Material zu ermöglichen;

10 b) Entfernen des nicht gebundenen Initiators durch Waschen oder Verdünnen;

c) Inkontaktbringen des biologischen Materials in vitro mit einem wasserlöslichen, nicht-toxischen biokompatiblen Makromer, das wenigstens zwei über freie Radikale polymerisierbare Substituenten aufweist, wobei das Makromer ein Molekulargewicht von wenigstens 400 hat; und

15 d) Exponieren des biologischen Materials gegen ein Agens, das den genannten Initiator aktiviert, um eine Polymerisation der Makromere zu bewirken, wodurch ein Polymergel mit einem Polymerisationsgrad von über 10 gebildet wird.

3. Verfahren nach Anspruch 2, wobei das biologische Material aus der Gruppe ausgewählt ist, die aus Säugetierzellen, subzellulären Organellen, subzellulären Komponenten und Aggregaten von Säugetierzellen besteht.

- 20 4. Verfahren nach Anspruch 1 oder 2, wobei die über freie Radikale polymerisierbaren Substituenten Kohlenstoff-Kohlenstoff-Doppel- oder -Dreifachbindungen enthalten.

- 25 5. Verfahren nach Anspruch 1 oder 2, wobei der Initiator zusammen mit einem nicht-toxischen Katalysator verwendet wird.

- 30 6. Verfahren nach einem beliebigen der vorhergehenden Ansprüche, wobei das wasserlösliche Makromer aus der Gruppe ausgewählt ist, die besteht aus Poly(ethylenglycol), Poly(ethylenoxid), Poly(vinylalkohol), Poly(vinylpyrrolidon), Poly(ethyloxazolin) oder einem Block- oder Random-Copolymer davon, das zwei oder mehr über freie Radikale polymerisierbare Substituenten aufweist.

- 35 7. Verfahren nach Anspruch 2, wobei das wasserlösliche Makromer aus der Gruppe ausgewählt ist, die besteht aus Poly(aminosäuren), Polysacchariden, Proteinen oder einem Block- oder Random-Copolymer davon, das zwei oder mehr über freie Radikale polymerisierbare Substituenten aufweist.

8. Verfahren nach Anspruch 7, wobei das Polysaccharid aus der Gruppe ausgewählt ist, die besteht aus Alginat, Hyaluronsäure, Chondroitinsulfat, Dextran, Dextransulfat, Heparin, Heparinsulfat, Heparansulfat, Chitosan, Gelangummi, Xanthangummi, Guarummi und κ-Carrageenan.

- 40 9. Verfahren nach Anspruch 7, wobei das Protein aus der Gruppe ausgewählt ist, die aus Gelatine, Collagen, Albumin, Zein und Elastin besteht.

10. Verfahren nach einem beliebigen der vorhergehenden Ansprüche, wobei das Gel aus Makromeren hergestellt wird, die ein durch Acrylat terminiertes Poly(ethylenglycol) umfassen.

- 45 11. Verfahren nach Anspruch 1 oder 2 zur Verkapselung eines biologisch aktiven Moleküls, wobei das biologisch aktive Molekül aus der Gruppe ausgewählt ist, die aus Peptiden, Polysacchariden, Nucleinsäuren, organischen Arzneimitteln und anorganischen Arzneimitteln besteht.

- 50 12. Verfahren nach Anspruch 1 oder 2, wobei der Initiator der Polymerisation aus der Gruppe ausgewählt ist, die besteht aus einem Eosinfarbstoff, einem substituierten Eosinfarbstoff, Eosin Y, Ethyleosin, Riboflavin, Acetophenon, einem substituierten Acetophenon, einem Fluoresceinfarbstoff, einem substituierten Fluoresceinfarbstoff, Kampferchinon, Bengalrosa, Methylengrün, Methylenblau, Acridinorange, Erythrosin, Phloximin, Thionin, Xanthinfarbstoffen und Thioxanthinfarbstoffen.

- 55 13. Verfahren nach Anspruch 5, wobei der Katalysator ein Amin ist.

14. Verfahren nach Anspruch 13, wobei das Amin aus der Gruppe ausgewählt ist, die besteht aus Triethanolamin,

Triethylamin, Ethanolamin, N-Methyldiethanolamin, N,N-Dimethylbenzylamin, Dibenzylamin, N-Benzylethanolamin, N-Isopropylbenzylamin, Tetramethylethylendiamin, Lysin, Ornithin, Histidin und Arginin.

- 5 **15.** Verfahren nach Anspruch 1 oder 2, wobei die Polymerisation durch Licht mit einer Wellenlänge zwischen 320 nm und 800 nm initiiert wird.
- 10 **16.** Verfahren nach Anspruch 15, wobei das Licht eine Wellenlänge von 514 nm oder 365 nm hat.
- 15 **17.** Verfahren nach Anspruch 3, wobei der nicht gebundene Initiator durch eine Verdünnung mit der Makromerlösung entfernt wird, so dass die Polymerisation nur an der Oberfläche der Säugetierzelle, der subzellulären Organelle, der subzellulären Komponente oder des Aggregats von Säugetierzellen erfolgt.
- 20 **18.** Verfahren nach Anspruch 1, wobei die Makromerlösung geformt und dann polymerisiert wird.
- 25 **19.** Verfahren nach Anspruch 1, wobei das Gel eine Stützstruktur enthält.
- 30 **20.** Verfahren nach Anspruch 1, wobei das Polymer so ausgewählt und die Polymerisation so gesteuert wird, dass die gewünschte Permeabilität um das verkapselte biologische Material oder den biokompatiblen Träger herum erzeugt wird.
- 35 **21.** Verfahren nach Anspruch 1, wobei das Makromer auf die Oberfläche eines dreidimensionalen Gegenstandes geschichtet wird und die beschichtete Oberfläche zur Initiation der Polymerisation des Makromers mit Licht bestrahlt wird.
- 40 **22.** Verfahren nach Anspruch 1, wobei ein photopolymerisierbares Polykation an das biologische Material oder den Träger, das bzw. der verkapstelt wird, voradsorbiert wird, um die Haftung des Gels auf dem biologischen Material oder Träger zu erhöhen.
- 45 **23.** Verfahren nach Anspruch 1 oder 2, wobei das biologische Material aus primären Säugetierzellen oder etablierten Säugetier-Zelllinien, subzellulären Organellen und subzellulären Komponenten, die keine Organellen sind, ausgewählt ist.
- 50 **24.** Verfahren nach Anspruch 23, wobei die Zelllinie ausgewählt ist aus Inselzellen des Pankreas, menschlichen Vorhautfibroblasten, Chinese-Hamster-Ovary-Zellen, Zellen von Beta-Zell-Insulinomen, lymphoblastoiden leukämischen Zellen, 3T3-Mausfibroblasten, Dopamin-sekretierenden Zellen des ventralen Mesencephalons, neuroblastoiden Zellen, Zellen des Nebennierenmarks und T-Zellen.
- 55 **25.** Verfahren nach Anspruch 1, wobei das biologische Material zuerst in einer Mikrokapsel verkapstelt wird.
- 60 **26.** Verfahren nach Anspruch 25, wobei die Mikrokapsel ionisch koagulierbare oder thermisch koagulierbare Polymere umfasst, die für das verkapselte Material nicht toxisch sind.
- 65 **27.** Verfahren nach Anspruch 1, wobei die Makromerlösung einen Beschleuniger zur Erhöhung der Polymerisationsgeschwindigkeit aufweist.
- 70 **28.** Verfahren nach Anspruch 27, wobei der Beschleuniger ein kleines Molekül umfasst, das eine Allyl-, Vinyl- oder Acrylatgruppe enthält.
- 75 **29.** Verfahren nach Anspruch 28, wobei der Beschleuniger aus der Gruppe ausgewählt ist, die besteht aus N-Vinylpyrrolidon, 2-Vinylpyridin, 1-Vinylimidazol, 9-Vinylcarbazol, Acrylsäure und 2-Allyl-2-methyl-1,3-cyclopentandion.
- 80 **30.** Verfahren nach Anspruch 1, wobei die Makromermischung eine wässrige Lösung ist.
- 85 **31.** Biologisches Material oder biokompatibles Trägermaterial, das durch ein Verfahren nach Anspruch 1 erhältlich ist, oder ein biologisches Material, das durch ein Verfahren nach Anspruch 2 erhältlich ist, für eine Verwendung in der Medizin.
- 90 **32.** Verwendung eines biologischen Materials oder biokompatiblen Trägermaterials, das durch ein Verfahren nach

Anspruch 1 erhältlich ist, oder eines biologischen Materials, das durch ein Verfahren nach Anspruch 2 erhältlich ist, bei der Herstellung eines Medikaments zum Einsatz bei der Behandlung metabolischer Defekte oder Erkrankungen.

- 5 **33.** Verwendung einer Makromermischung, wie sie in einem beliebigen der Ansprüche 1, 2, 4 bis 16, 18 bis 20, 22 und 27 bis 30 beansprucht wird, bei der Herstellung eines Medikaments zur Behandlung metabolischer Defekte oder Erkrankungen.
- 10 **34.** Verwendung einer Makromermischung, wie sie in einem beliebigen der Ansprüche 1, 2, 4 bis 16, 18 bis 20, 22 und 27 bis 30 beansprucht wird, bei der Herstellung eines Medikaments zur Verwendung als Klebstoff, als Gewebebestütze oder als Füllung, oder als Sperre zur Verhinderung der Wechselwirkung zwischen einer Zelle oder einem Gewebe mit einer anderen Zelle oder einem anderen Gewebe.

15 **Revendications**

- 1. Procédé non-cytotoxique pour encapsuler, sceller, tamponner ou supporter un matériau biologique ou pour préparer un substrat biocompatible, le procédé comprenant :
 - 20 a) fournir un mélange de macromères en mélangeant
 - (i) un macromère biocompatible hydrosoluble, polymère synthétique, comprenant au moins deux substituants polymérisables à radical libre, dans lequel le macromère est non-toxique et a une masse moléculaire d'au moins 400 ; et
 - (ii) un initiateur de polymérisation à radical libre non-toxique choisi parmi une lumière visible ou un initiateur à radical libre activable par une lumière ultraviolette à longueur d'onde longue ;
 - 25 b) revêtir un matériau biologique ou un substrat in vitro avec le mélange de macromères, dans lequel le matériau biologique est choisi dans le groupe comprenant des cellules de mammifères, des organites subcellulaires, des composants subcellulaires et des agrégats de cellules de mammifères et le substrat est choisi parmi des microcapsules, des matrices tissées, des matrices poreuses et des implants prothétiques ; et
 - 30 c) exposer le matériau biologique revêtu ou le substrat revêtu à une lumière visible ou ultraviolette à longueur d'onde longue pour provoquer la polymérisation des macromères, formant ainsi un gel polymère avec un degré de polymérisation supérieur à 10.
- 35 2. Procédé non-cytotoxique pour encapsuler, sceller, tamponner ou supporter un matériau biologique, le procédé comprenant :
 - 40 a) mise en contact d'un matériau biologique avec une solution d'un initiateur de polymérisation à radical libre non-cytotoxique choisi dans le groupe comprenant des initiateurs activables à la lumière visible ou ultraviolette à longueur d'onde longue, pour permettre la liaison de l'initiateur au matériau biologique ;
 - 45 b) élimination de l'initiateur non lié par lavage ou dilution ;
 - c) mise en contact du matériau biologique in vitro avec un macromère biocompatible non-toxique hydrosoluble comprenant au moins deux substituants polymérisables à radical libre, le macromère ayant une masse moléculaire d'au moins 400 ; et
 - d) l'exposition du matériau biologique à un agent activant ledit initiateur pour provoquer la polymérisation des macromères, formant ainsi un gel polymère avec un degré de polymérisation supérieur à 10.
- 50 3. Procédé selon la revendication 2, dans lequel le matériau biologique est choisi dans le groupe comprenant des cellules de mammifères, des organites subcellulaires, des composants subcellulaires et des agrégats de cellules de mammifères.
- 55 4. Procédé selon la revendication 1 ou 2, dans lequel les substituants polymérisables à radical libre contiennent des liaisons carbone-carbone doubles ou triples.
- 5. Procédé selon la revendication 1 ou 2, dans lequel l'initiateur est utilisé conjointement avec un catalyseur non-toxique.

6. Procédé selon l'une quelconque des revendications précédentes, dans lequel le macromère hydrosoluble est choisi dans le groupe comprenant le polyéthylène glycol, l'oxyde de polyéthylène, l'alcool de polyvinyle, la polyvinylpyrrolidone, la polyéthyloxazoline, ou un copolymère séquencé ou aléatoire de ceux-ci, comprenant deux substituants polymérisables à radical libre ou plus.
- 5 7. Procédé selon la revendication 2, dans lequel le macromère hydrosoluble est choisi dans le groupe comprenant des polyamino-acides, des polysaccharides, des protéines ou un copolymère séquencé ou aléatoire de ceux-ci, comprenant deux substituants polymérisables à radical libre ou plus.
- 10 8. Procédé selon la revendication 7, dans lequel le polysaccharide est choisi dans le groupe comprenant l'alginate, l'acide hyaluronique, le sulfate de chondroïtine, le dextrane, le sulfate de dextrane, l'héparine, le sulfate d'héparine, le sulfate d'héparane, le chitosane, la gomme gellane, la gomme xanthane, la gomme guar et la carragénine k.
- 15 9. Procédé selon la revendication 7, dans lequel la protéine est choisie dans le groupe comprenant la gélatine, le collagène, l'albumine, la zéine et l'élastine.
10. Procédé selon l'une quelconque des revendications précédentes, dans lequel le gel est préparé à partir de macromères comprenant un polyéthylène glycol avec une terminaison acrylate.
- 20 11. Procédé selon la revendication 1 ou 2, pour encapsuler une molécule biologiquement active, dans lequel la molécule biologiquement active est choisie dans le groupe comprenant des peptides, des protéines, des polysaccharides, des acides nucléiques, des médicaments organiques et des médicaments inorganiques.
- 25 12. Procédé selon la revendication 1 ou 2, dans lequel l'initiateur de polymérisation est choisi dans le groupe comprenant un colorant éosine, un colorant éosine substitué, l'éosine Y, l'éthyléosine, la riboflavine, l'acétophénone, une acétophénone substituée, un colorant fluorescéine, un colorant fluorescéine substitué, une camphorquinone, le rose Bengale, le vert de méthylène, le bleu de méthylène, l'acridine orange, l'érythrosine, la phloximine, la thionine, des colorants xanthine et des colorants thioxanthine.
- 30 13. Procédé selon la revendication 5, dans lequel le catalyseur est une amine.
14. Procédé selon la revendication 13, dans lequel l'amine est choisie dans le groupe comprenant la triéthanolamine, la triéthylamine, l'éthanolamine, la N-méthyl-diéthanolamine, la N,N-diméthyl-benzylamine, la dibenzylamine, la N-benzyléthanolamine, la N-isopropyl-benzylamine, la tétraméthyl-éthylène-diamine, la lysine, l'ornithine, l'histidine et l'arginine.
- 35 15. Procédé selon la revendication 1 ou 2, dans lequel la polymérisation est initiée par une lumière ayant une longueur d'onde comprise entre 320 et 800 nm.
- 40 16. Procédé selon la revendication 15, dans lequel la lumière a une longueur d'onde de 514 nm ou de 365 nm.
17. Procédé selon la revendication 3, dans lequel l'initiateur non lié est éliminé par dilution avec la solution de macromère de telle manière que la polymérisation se produit seulement à la surface de la cellule de mammifère, de l'organite subcellulaire, du composant subcellulaire ou de l'agrégat de cellules de mammifères.
- 45 18. Procédé selon la revendication 1, dans lequel la solution de macromère est formée puis polymérisée.
19. Procédé selon la revendication 1, dans lequel le gel contient une structure de support.
- 50 20. Procédé selon la revendication 1, dans lequel le polymère est choisi et la polymérisation est contrôlée pour produire une perméabilité souhaitée autour du matériau biologique ou du substrat biocompatible encapsulé.
21. Procédé selon la revendication 1, dans lequel le macromère est déposé à la surface d'un objet tridimensionnel et la surface revêtue est irradiée à la lumière pour initier la polymérisation du macromère.
- 55 22. Procédé selon la revendication 1, dans lequel un polycation photopolymérisable est pré-adsorbé sur le matériau biologique ou le substrat étant encapsulé pour accroître la fixation du gel au matériau biologique ou au substrat.

23. Procédé selon la revendication 1 ou 2, dans lequel le matériau biologique est choisi parmi des lignées primaires ou établies de cellules de mammifères, des organites subcellulaires, et des composants subcellulaires qui ne sont pas des organites.

5 24. Procédé selon la revendication 23, dans lequel la lignée cellulaire est choisie parmi les cellules des îlots de Langerhans du pancréas, les fibroblastes du prépuce de l'homme, les cellules de l'ovaire de hamster chinois, les insulomes de cellules bêta, les cellules de leucémie lymphoblastique, les fibroblastes de souris 3T3, les cellules du mésencéphale antérieur sécrétant de la dopamine, les neuroblastes, les cellules de la médullosurrénale et les cellules T.

10 25. Procédé selon la revendication 1, dans lequel le matériau biologique est d'abord encapsulé dans une microcapsule.

26. Procédé selon la revendication 25, dans lequel la microcapsule est composée des polymères coagulables par voie ionique ou thermique, qui sont non-toxiques pour le matériau encapsulé.

15 27. Procédé selon la revendication 1, dans lequel la solution de macromère comprend en outre un accélérateur pour accélérer la vitesse de polymérisation.

20 28. Procédé selon la revendication 27, dans lequel l'accélérateur comprend en outre une petite molécule contenant un groupe allyle, vinyle ou acrylate.

29. Procédé selon la revendication 28, dans lequel l'accélérateur est choisi dans le groupe comprenant la N-vinyl-pyrrolidinone, la 2-vinyl-pyridine, le 1-vinyl-imidazole, le 9-vinyl-carbazole, l'acide acrylique et la 2-allyl-, 2-méthyl-, 1,3-cyclopentane-dione.

30 30. Procédé selon la revendication 1, dans lequel le mélange de macromères est une solution aqueuse.

31. Matériau biologique ou substrat biocompatible susceptible d'être obtenu par un procédé selon la revendication 1, ou matériau biologique susceptible d'être obtenu par un procédé selon la revendication 2, pour une utilisation en médecine.

32. Utilisation d'un matériau biologique ou d'un substrat biocompatible susceptible d'être obtenu par un procédé selon la revendication 1, ou matériau biologique susceptible d'être obtenu par un procédé selon la revendication 2, dans la préparation d'un médicament destiné à être utilisé dans le traitement d'anomalies ou de maladies métaboliques.

35 33. Utilisation d'un mélange de macromères selon l'une quelconque des revendications 1, 2, 4 à 16, 18 à 20, 22 et 27 à 30, dans la fabrication d'un médicament destiné au traitement d'anomalies ou de maladies métaboliques.

40 34. Utilisation d'un mélange de macromères selon l'une quelconque des revendications 1, 2, 4 à 16, 18 à 20, 22 et 27 à 30, dans la fabrication d'un médicament pour une utilisation comme adhésifs, comme supports tissulaires ou comme tampons, ou comme barrières pour empêcher l'interaction d'un tissu cellulaire avec une autre cellule ou un autre tissu.
